5.5 Assessment of Sibling Needs and its implication in Planning IFSP 5.5.1. Sibling Need

89%**MATCHING BLOCK 186/203****SA**

SEID -31 PDF.pdf (D127037695)

The presence of an individual with intellectual disability in the family call for a lot of adjustments on the part of the parents, siblings and other significant family members (Peshwaria & Menon,1991). Identifying and meeting individual needs of various members in the family is the only way to strengthen the family having a child with intellectual disability. Beyond the typical needs experienced by siblings with the birth of a brother or sister, increased stress and additional needs for support are experienced by siblings having brothers or sisters with disability. These unique needs may take the form of family support, assistance, information etc. Thus, to strengthen families having individuals with intellectual disabilities, interventions must recognize the feelings and needs of the siblings. (Turnbull & Turnbull,1990). Although siblings may not always explicitly reveal their needs,

the research does suggest

93% MATCHING BLOCK 187/203 SA SEID -31 PDF.pdf (D127037695)

that siblings of persons with handicaps do have a number of special needs related to 202 themselves, their families, and the community. However till date very few attempts have been made to empirically study the needs of siblings having brother or sister with intellectual disability. Anecdotal reports have been the main source of identifying needs expressed by siblings.

Powell & Ogle (1985) contended that special concerns and unique needs will vary from sibling to

100% MATCHING BLOCK 188/203 SA SEID -31 PDF.pdf (D127037695)

sibling based on a number of individual characteristics of the family system.

Broad interpretation of the research findings indicate that

83% MATCHING BLOCK 189/203 SA SEID -31 PDF.pdf (D127037695)

siblings of children with handicaps have a range of needs from knowing the cause of handicaps, how to get along with their handicapped sibling better, what to tell their friends about their handicapped sibling, future role , to dealing with parental expectations. Children are a source of strength for parents. This relationship assumes even greater significance when there is a handicapped member in the family and especially for a country like India where there are no special security systems and siblings naturally assume the role of guardianship of their brother/ sister with intellectual

disabilities after the death of their parents. Within

78% MATCHING BLOCK 191/203 SA SEID -31 PDF.pdf (D127037695)

this context, to strengthen this natural resource of support i.e., the sibling by identifying and meeting their unique needs becomes imperative.

The empirical understanding of these siblings having brothers/sisters with intellectual disability in Indian families in terms of their impact needs and involvement are far from adequate and hence need priority. 5.5.2 Assessment: The needs of siblings having a brother /sister with intellectual disability will be assessed by using a specifically developed semi-structured interview schedule NIMH FAMILY NEEDS SCHEDULE (Siblings) shortly known as NIMH- FAMNS(Siblings). The NIMH-FAMNS (Siblings) consisted of 16 different needs. The score of each item on the schedule ranged from 0 to 2 (0-no need, 1- Little, 2- Very much need) so that higher the score, greater is the intensity of the need expressed by the sibling. According to NIMH-FAMNS (Sibling) the various sibling needs are as follows: 1. Information: condition 2. Expected achievement 3. Training regarding the sibling management. 4. Hostel placement provision and information. 5. Information explaining the condition. 6. More time: to self. 7. Help: Future Plan.

203 8. Information: Resources. 9. Information about the training programme. 10. Expecting equal attention. 11. Normal expect: Parents. 12. Help: mediate family. 13. Information: Motivate. 14. Awareness programme. 15. Information: Government Benefit. 16. Others 5.5.3 Implication in planning IFSP: Unlike parents siblings also have a greater role in IFSP for the eligible child. - Siblings do require information on the condition of their brother/sister with intellectual disability. They also require knowledge and skills to train and learn to manage behavior problems of their affected brother/sister effectively. To meet such needs of siblings, needs based intervention programmes such as Behaviour modification workshops could be conducted. - Siblings do not only require help in meeting the needs of their brother. /sister with intellectual disability but they also require help for themselves in planning for their future. - Sibling groups could be initiated to help siblings share their concerns with each other. Interactions between siblings could contribute immensely in resolving their emotional reactions and help learn from each other's experiences, the ways of coping with common situations encountered by them. Individual and group counselling programmes for siblings can be of great help. - Parents and family members need to become aware of the special needs of siblings. Non-handicapped siblings i.e. brothers and sisters may also need to understand each others' needs and help share the extra responsibilities equally. - Intervention programmes should emphasize and encourage involvement of non- handicapped siblings with their brother/sister with intellectual disability right from the beginning when a child with intellectual disability is identified in the 204 family. This would help shape up siblings to accept, adjust and also contribute constructively in strengthening the families. - Parents are generally the decision makers for their children especially so when the children are still young. Hence, parental acceptance of siblings' involvement becomes one of the crucial factors in facilitating the initiation or conduct of intervention programmes with the siblings. Parents may need to be convinced on the merits of sibling involvement as also that, such an involvement will not adversely affect the non-handicapped sibling. 5.6 Assessment

100%

MATCHING BLOCK 190/203

W

of Extended Family Needs and its implication in Planning IFSP 5.6.1

Need of grandparents: Grandparents constitute important part of the environment that the index child must inevitably interact. Typically in India ,being elders in the family ,grandparents to a large extent influence the decision making related to child care ,nursing, nutrition and wide ranging matters in family life. Depending upon their resources, the availability of time, their age and physical health, most often the grandparents are drawn into the role of caregivers or supervisors of caregivers. With rapid urbanization, even though the traditional joint family system is fast disintegrating, yet grandparents continue to play an important and significant role which has direct bearing on the child with intellectual disability and the family. Following are the categories related to the needs reported by grandparents of children with intellectual disability: 1. Cure: Intellectual disability – Looking for a treatment or a therapy that will cure the condition of intellectual disability. 2. Guidance: Help family – Guidance from the therapists as to how they can help the family. 3. Information: Government Benefits – From where and what are the benefits available from the Government for such children. 4. Care: Future – Future social security of the grandchild. 5. Information: Child management – Availability of training programmes to help 205 them manage their grandchild. 6. Training Communication – Training programme in language and communication for the grandchild. 7. Cause: Intellectual Disability – Interested to know what caused the condition. 8. Sensitivity : Professionals – Want. 9. Information: resources – From whom and where to turn for help. 5.6.2 Assessment of grand parents need: The needs of grandparents having a grandchild with intellectual disability will be assessed by using a specifically developed semi- structured interview schedule NIMH FAMILY NEEDS SCHEDULE (Grandparents) shortly known as NIMH-FAMNS(Grandparents).The NIMH-FAMNS (Grandparents) consisted of 9 different needs. The score of each item on the schedule ranged from 0 to 2 (0-no need, 1- Little, 2- Very much need) so that higher the score, greater is the intensity of the need expressed by the sibling. 5.6.3 Implication in planning IFSP: Any work on the families would be incomplete without taking into account the role of grandparents. Grandparents are one of the significant natural support providers to a family having a child with intellectual disability, helpful for developing IFSP - Grandparents are a great natural resource/support for the families having persons with intellectual disability and hence their role needs to be strengthened. It has been reported by parents that acceptance and support by grandparents' especially parental grandparents is considered as an important facilitator in coping. - Grandparents are involved in many ways in providing support to the family yet they have expressed the need for further help and guidance from professionals' as to how they can contribute better which must be meet. - Grandparents do

76%

MATCHING BLOCK 193/203

SA

THESIS Vaniaritakula Social Work.docx (D19105024)

get affected in many ways because of having a grandchild with intellectual disability.

Help in mitigating such effects must start early with grandparents and strategies for help included in the family intervention programmes. - Grandparents though have emotional reactions as the strongest impact, yet, while expressing needs they did not seek any help for the same. The need to
206 resolve or understand these emotional reactions could be explored if necessary during counselling programme. - Grandparents too have several needs because of having grandchild with intellectual disability in the family. These needs require to be identified and individualized intervention programmes have to be worked out to meet such needs. - All the family members including the parents and siblings of the child with intellectual disability must become aware of the grandparents needs and involve themselves in meeting the grandparents' needs. When professionals work towards mitigating the impact and help meeting the needs of grandparents, it would help strengthen grandparents to involve more constructively to the wellbeing of the grandchild with mental retardation and the whole family. Family counselling would go a long way in meeting some of the needs. - Grandparents could be brought together in a group to share their concern with each other. Interactions amongst affected grandparents could contribute immensely in resolving emotional reactions and learning from each other's experience in coping with certain common situations. - Professionals working and interacting with the families do need to equip themselves with effective counselling skills to communicate the child's condition and also to have better relationships with all the family members. - Training programmes for the grandparents could be conducted as per identified needs of grandparents. This would equip them with the knowledge and skills and enable grandparents to spend time with their grandchild more usefully and effectively. Other than the grandparents there are little need for cousin brothers and other uncle, aunts those who are continuously living with the family which include the entire family member's need are discussing throughout this chapter. Acceptance of these children and involve with them will have greater

implication in planning IFSP. 5.7 Assessment of Family and Community Resources for Inclusion and Strengthening of Family 5.7.1. Assessment of family –

In this point we explore the context and process of family assessment with in early intervention programme for children with disabilities or developmental delays. Family
207 assessments are now a routine, indeed mandated, practice in early intervention programmes. Three primary reasons can be advanced with disabilities. 1. Family assessment recognizes explicitly the need to examine the children's development within their most powerful context, that of the family. 2. Family assessment is grounded in the belief that parents can benefit from focused attention on their capacities for providing a nurturing, informed and attentive environment for their children with disabilities. 3. There is an increasing recognition that the intensity and specificity of early intervention programme need to be tailored to the characteristics and functioning of the family in light of the child's disability or risk status. (Guralnick, 1998) 5.7.2 Assessment of Community Resources Resource assessment is central to economic development planning since local resources are the primary means through which communities can effect economic development outcomes. Resource Assessment Goals: • Identify critical resources and assets • Evaluate their potential and current contribution to development goals • Define ways to more effectively apply them Five resource areas to evaluate: (1) Land, facilities and infrastructure that supply (and sustain) the physical assets and systems that support economic activity (2) Human capital and labour force resources, including the education and training system, that provide the skills and talent to form, manage and operate enterprises. (3) Capital resources that finance businesses, community facilities and other community needs. (4) Technology resources that contribute new products and processes, technical know-how, and best practices to the economy. (5) Organizational capacity and relationships to undertake economic development activities.

208 Documentation, Recording and Reporting Assessment Result a) Components of assessment report: Documentation and Recording - The major components of assessment report which are needed to record for documentation are as follows: 1.

96% MATCHING BLOCK 194/203 SA SEID -31 PDF.pdf (D127037695)

Identification Data: All essential demographic information about the student: full name, address, date

of

81% MATCHING BLOCK 195/203 SA SEID -31 PDF.pdf (D127037695)

birth, and so forth. 2. Reason for referral: The basis for and source of the referral. 3. Relevant background: Significant information about the student's medical, developmental, educational and socio cultural background. 4. Behavioural Observations: Descriptions of the student's behaviour during assessment. 5. Assessment result and discussion: Scores and other results in pertinent areas, such as reading, mathematics, and so forth. 6. Summary and conclusions: A brief statement of the level of performance and strength and weakness in the areas assessed. 7. Recommendations: The goals and objectives, special services, and service delivery models appropriate for the student's educational needs. 8. Data Sheet: All the formal and informal results for independent analysis and reference.

b) General principle of reporting–

96% MATCHING BLOCK 196/203 SA SEID -31 PDF.pdf (D127037695)

The interpretation and reporting of assessment results are guided by a set of general principles – a)

Follow a structured format. b) Report only relevant data c)

88% MATCHING BLOCK 197/203 SA SEID -31 PDF.pdf (D127037695)

Report information once and then mention it only as needed. d) Avoid making

recommendations or giving ideas for solutions throughout the report. e) Report facts and data accurately and in a simple way. f) Insert sensitive information tactfully. g)

100% MATCHING BLOCK 198/203 SA SEID -31 PDF.pdf (D127037695)

Note the source of any information and report the data accurately. 209

h) During reporting data from previous assessment,

79% MATCHING BLOCK 199/203 SA SEID -31 PDF.pdf (D127037695)

do so briefly and with full reference to the source. i) Mention the absence of critical data, such as recent visual and hearing assessments. j) Report any test administration errors

or

92%

MATCHING BLOCK 200/203

SA

SEID -31 PDF.pdf (D127037695)

problems and reservations about the findings. k) Consider information about instructional factors in the classroom and non- instructional correlates (medical, social,

and cultural). l) Address discrepancies between data and present possible explanations. m) Statistical and clinical analysis should be done during interpreting test results. n) Selectively use of theoretical constructs. o) Keep a variety of stylistic points in mind. Interpretation and reporting the results require both an excellent understanding of data as well as a good grasp of communication skills. 5.8 "Check Your Progress" 1. What do you mean by family?

All_Chapter_Final_DKT_Ph.d_Thesis_Revised.docx (D143306060)

Families are critical agents in the care, management and habilitation of individuals with intellectual disability. Parents, sibling and other significant family members are increasingly, being involved in the training and habilitation of the individuals with intellectual disability. The underlying concept of family centered intervention is that children's functioning can be maximized by providing services that are designed to enhance the effectiveness of their families. Families are interactive, interdependent systems with individual members reciprocally affecting each other. ●●●●●

Consequently, any events or changes that affect one member of the family will directly or indirectly affect all other members and therefore affect the family as a whole. Family needs are identified by analyzing the needs of every family members need i.e; parental needs, sibling need and grandparent's need. NIMH Family Needs Schedule (NIMH-FAMNS) are used to assess the needs of various family member according to the relationship which are available in three separate checklists. ●●●●● Individual Family service Plan (IFSP) plan required by PL 99-457 that includes the related needs of the family of the child with disabilities. The regulation require that an IFSP or Individual Family service Plan, be developed for each infant or toddler and its family. Family members are taught and trained about

211 the identification of the assets of the child, need of their child with disabilities, their involvement with them, choice of those children, hope with these children. ●●●●● Intervention should be individualized for parents and families as per their individual needs. ●●●●● Community is also plays a major role to develop a child. So there is a need of assessing the

community resources i.e.; physical, financial, human, technical and organizational resources. ●●●●● A community needs assessment identifies the strengths and resources available in the community to meet the needs of children, youth, and families. The assessment focuses on the capabilities of the community, including its citizens, agencies, and organizations. It provides a framework for developing and identifying services and solutions and building communities that support and nurture children and families. ●●●●●

Planning for Vocational Transition : the Process This is the important phase of a transition model. Transition programme would have no meaning without specific planning. Formal individualized student plans It is essential to develop a formal, individualized transition plan for every student with intellectual disability. Formal plan should specify the objectives to be acquired. The plan should include annual goals and short term objectives that reflect skills required to function on the job, at home and in the community. Transition plan should be comprehensive in scope. In addition to specific job skill training, students must also be prepared to use community services effectively, manage money, and travel to and from work place independently. Plans must take care of all these skill areas to meet the comprehensive needs of the students and at the same time should be individualized. Each individual requires a different set of post-school services. Transition plans must also be longitudinal in nature. Participation of all individuals and agencies involved in the transition process during the initial development

the plan is required till the final placement. The plan initially should be for a longer period and should then be modified once in a year. ØØØØ Consumer input
 Wherever appropriate, the person with ID should be consulted for his views and options as he is the consumer of the plan proposed. When the person with intellectual disability is not capable of making decision, the parent or primary caregiver becomes the consumer to represent the student concerned, Therefore, parental involvement in vocational transitional plans is important. They should be made aware of the employment alternatives available to their children. They must acquire knowledge and skills required to participate effectively in transitional planning. Systematically planned parent education programs will improve the effectiveness and duration of parent involvement. Parent education meeting should be conducted by the school personnel for the purpose of enhancing parental involvement. The meeting should.

- Orient the parents to the community agencies providing post-school services to handicapped youth.
- Familiarize parents with specific responsibilities of special education, vocational education and vocational rehabilitation in the vocational transition process. ●●●●

Prepare parents to work with various agencies to develop transition plans and to apply for future services. 164

Inter-agency co-operation It refers to coordinated efforts across different agencies like schools, rehabilitation services and vocational training centers so as to ensure the delivery of appropriate, non-duplicated services to each student (Morton et al. 1983) However, it is a difficult attempt. Since agencies differ widely in their opinion, services continue to be duplicated. Solutions to these problems are yet to come up. ØØØØØ Employment outcome Employment outcome is the outgrowth of appropriate secondary special educational programme and a meaningful transition plan. As a result of the implementation of individualize transition plan the trainee should be in a position to work in open employment, supported employment, sheltered employment or self-employment setup. It is essential that communities should provide different vocational alternatives, in order to make transition programme a success. ØØØØØ Necessity of follow-up services Though outcome stage is the final stage in the transition model, the responsibility of the special educator does not end with this. In order to monitor the transition effectively, it is the essential to follow-up the individuals-who are placed on jobs in regular interval. It is also essential to ensure job retention by the person concerned. Here, we have to collect information about the student's perception of his/her present job status, parents' satisfaction and the employer's evaluation of his/her work performance. The follow up services in addition to helping the students in retaining the job will help the professional in gathering information about the effectiveness of the transition programme. 4.5

Before deciding the training place, nature and training programme, it is essential to know a few aspects like:- 181

- The type of toilet used by the family
- The person would be involved in training
- The cultural belief for toileting
- Cleaning methods after toileting etc.

Developing teaching materials for the student must be based on the resources of the parents; if the parents are affordable to purchase highly costly materials then it will be worthwhile to prescribe such materials. On the other hand, the poor people could be advised to develop teaching materials

The presence of an individual with intellectual disability in the family call for a lot of adjustments on the part of the parents, siblings and other significant family members (Peshwaria & Menon,1991). Identifying and meeting individual needs of various members in the family is the only way to strengthen the family having a child with intellectual disability. Beyond the typical needs experienced by siblings with the birth of a brother or sister, increased stress and additional needs for support are experienced by siblings having brothers or sisters with disability. These unique needs may take the form of family support, assistance, information etc. Thus, to strengthen families having individuals with intellectual disabilities, interventions must recognize the feelings and needs of the siblings. (Turnbull & Turnbull,1990). Although siblings may not always explicitly reveal their needs,

3 Netaji Subhas Open University From the Vice-Chancellor's Desk Dear Students, from this Academic Session (2015-17) the Curriculum and Course Structure of B. Ed.- Special Education have been thoroughly revised as per the stipulations which featured in the Memorandum of Understanding (MoU) between the Rehabilitation Council of India (RCI) and the National Council for Teacher Education (NCTE). The newly designed course structure and syllabus is comprehensive and futuristic has, therefore, been contextualized and adopted by NSOU from the present academic session, following the directives of the aforesaid national statutory authorities. Consequent upon the introduction of new syllabus the revision of Self Instructional Material (SIM) becomes imperative. The new syllabus was circulated by RCI for introduction in the month of June, 2015 while the new session begins in the month of July. So the difficulties of preparing the SIMs within such a short time can easily be understood. However, the School of Education of NSOU took up the challenge and put the best minds together in preparing SIM without compromising the standard and quality of such an academic package. It required many rigorous steps before printing and circulation of the entire academic package to our dear learners. Every intervening step was meticulously and methodically followed for ensuring quality in such a time bound manner. The SIMs are prepared by eminent subject experts and edited by the senior members of the faculty specializing in the discipline concerned. Printing of the SIMs has been done with utmost care and attention. Students are the primary beneficiaries of these materials so developed. Therefore, you must go through the contents seriously and take your queries, if any, to the Counselors during Personal Contact Programs (PCPs) for clarifications. In comparison to F2F mode, the onus is on the learners in the ODL mode. So please change your mind accordingly and shrug off your old mindset of teacher dependence and spoon feeding habits immediately.

4 I would further urge you to go for other Open Educational Resources (OERs) - available on websites, for better understanding and gaining comprehensive mastery over the subject. From this year NSOU is also providing ICT enabled support services to the students enrolled under this University. So, in addition to the printed SIMs, the e-contents are also provided to the students to facilitate the usage and ensure more flexibility at the user end. The other ICT based support systems will be there for the benefit of the learners. So please make the most of it and do your best in the examinations. However, any suggestion or constructive criticism regarding the SIMs and its improvement is welcome. I must acknowledge the contribution of all the content writers, editors and background minds at the SoE, NSOU for their respective efforts, expertise and hard work in producing the SIMs within a very short time. Professor (Dr.) Subha Sankar Sarkar Vice-Chancellor, NSOU

It allows us to observe and learn more about the surrounding world 10 than we do with the help of any of the four other senses. We use our eyes in almost every activity we perform, whether watching, reading, writing, working, viewing television, driving a cycle, and in countless other ways. It also allows us to see and interpret the shapes, colours and dimensions of objects in the world they reflect or emit. The eye is able to detect bright light or dim light, but it cannot sense object when light is absent. In the following sections

the structure and functions of human eye, vision development and process of seeing, principles of refraction and refractive errors, blindness and low vision

and other related concepts are discussed. 1.2 Objectives After going through the self-instructional materials in Sub-Unit 1, the learners will be able to: • Know about the

57% MATCHING BLOCK 7/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

structure and functions of human eye; • Understand normal vision development and process of seeing; • Understand the principles of refraction and refractive error; • Understand the blindness, impairment and low vision; • Understand the Concepts of Visual Acuity, Visual Field, Depth Perception, and Contrast Sensitivity. 1.3

Structure and Function of Human Eye 1.3.1 Structure of Human Eye The human

84% MATCHING BLOCK 5/112 W

eye is one of the most complex organs in our body. It is

amazing that something so small an organ can have so many working parts. But when you consider how difficult the task of providing vision really is, perhaps it's no wonder after all. The outer covering of the eyeball consists of a relatively tough, white layer called the sclera (or white part of the eye). Near the front of the eyeball, in the area protected by the eyelids, the sclera is covered by a thin, transparent membrane, known as conjunctiva, which runs to the edge of the cornea. The conjunctiva also covers the moist black surface of the eyelids and eyeballs (Figure: 1). Light enters the eyeball through the cornea, the clear, curved layer in front of the iris and pupil. The cornea serves as a protective covering for the front of the eye and also helps focus light on the retina at the back of the eye. After passing through the cornea, light travels through the pupil (the black dot in

44% MATCHING BLOCK 6/112

W

the middle of the eye). The iris—the 11 circular, coloured area of the eye that surrounds the pupil—controls the amount of light that enters into the eyeball. The

pupil dilates (enlarges) and constricts (shrinks) like the aperture of a camera lens as the amount of light in the immediate surroundings changes. The iris allows more light into the eye when the environment is dark and allows less light into the eye when the environment is bright. The size of the pupil is controlled by the actions of the pupillary sphincter muscle and dilator muscle. Figure 1: Schematic Diagram of Human Eye Behind the iris sits the lens. By changing its shape, the lens focuses light onto the retina. Through the action of small muscles, the lens becomes thicker to focus on nearby objects and thinner to focus on distant objects. The retina contains the cells that sense light (photoreceptors) and the blood vessels that nourish them. The most sensitive part of the retina is a small area called the macula, which has millions of tightly packed photoreceptors (the type called cones). The high density of cones in the macula makes the visual image detailed, just as a high-resolution digital camera has more megapixels, Each photoreceptor is linked to a nerve fibre. The nerve fibres from the photoreceptors are bundled together to form the optic nerve. The optic disk, the first part of the optic nerve, is at the back of the eye. The photoreceptors in the retina convert the image into electrical signals, which are carried to the brain by

12 the optic nerve. There are two main types of photoreceptors - cones and rods. Cones are responsible for sharp, detailed central vision and colour vision and are clustered mainly in the macula. The rods are responsible for night and peripheral (side) vision. Rods are more numerous than cones and much more sensitive to light, but they do not register colour or contribute to detailed central vision as the cones do. Rods are grouped mainly in the peripheral areas of the retina. The eyeball is divided into two sections, each of which is filled with fluid. The front section (anterior segment) extends from the inside of the cornea to

70% MATCHING BLOCK 8/112

SA SEVI-31 with glossary for alignment.docx (D127037367)

the front surface of the lens. It is filled with a fluid called the aqueous humor, which

nourishes the internal structures. The back section (posterior segment) extends from the back surface of the lens to the retina. It contains a jellylike fluid called the vitreous humor. The pressure generated by these fluids fills out the eyeball and helps maintain its shape. The anterior segment is divided into two chambers. The front (anterior) chamber extends from the cornea to the iris. The back (posterior) chamber extends from the iris to the lens. Normally, the aqueous humor is produced in the posterior chamber, flows slowly through the pupil into the anterior chamber, and then drains out of the eyeball through outflow channels located where the iris meets the cornea. Some important structural components of human eye and their functions are given below: 1.

45% MATCHING BLOCK 9/112

W

Sclera - Sclera is the white part of the eye which forms the larger portion of the eye ball. Function: a. It helps to maintain the shape of the eye. b. It supports delicate structures within the eye. 2.

Conjunctiva - a thin clear mucous membrane which covers the front of the sclera and follows around to line the inside of the eyelids is the Conjunctiva. Function: It covers the interior surface of lids and joins them to the eyeball. 3. Cornea - A crystal-clear window at the front of the eye is known as Cornea, it is a thin convex-concave living tissue which is kept moist by a thin film of tear and bathed on the posterior surface by the aqueous humour. It is kept smooth by blinking of the lids. Function: It permits the light to pass through and helps focusing it on the retina along with the lens.

13 4. Iris - The black disc beneath the cornea is Iris. The posterior surface of the iris is pigmented. The colour of the iris decides colour of the eye. Function: Muscle in the iris make the pupil larger or smaller. 5. Pupil: The black hole in the centre of the iris is Pupil. The pupils in both the eye- balls look black due to the darkness of the interior of the eye. Function: (a) It controls entry of light into the eye - In bright light, the circular muscles of the iris contract and the pupil becomes smaller to reduce the amount of light that enters into the eye, while in dark, muscles help the pupil to widen allowing more light to enter into the eye. 6. Anterior Chamber - is situated between the cornea and the iris. It is filled with clear fluid called the aqueous humour. Function: a. The aqueous humour keeps the posterior surface of the cornea moist. b. It plays a major role in the maintenance of the pressure of the eye. 7. Lens - Lens is situated behind the iris in the eye-ball. It is transparent and consists of an elastic capsule filled with clear material. It is suspended by transparent fibres of zonules. Function - Focusing the rays of light to the back of the eye. 8. Retina - it is the light sensitive membrane of nerves which lines the inner surface of the eye and consists of - (a) an outer layer of pigment epithelium, (b) inner portions of rods, cones and (c) connecting nerve cells. Function - It changes light waves into electrical impulses. 9. Vitreous Body - It is the clear, viscous liquid, like a jelly filled in the open area between the lens and retina. Function - This fluid basically holds the lens place and gives support to the eye coats. 10. Optic Nerves - the fine fibres arising from each nerve cell come out of the eye- ball through the optic nerve and join the fibres coming from the either eye at an interaction in the brain called 'chiasm'. Function - It carries impulses to the back of the brain where the consciousness of colour and shapes takes place. 11. Macula- It is a small area situated at the centre of the retina. It is the most sensitive visual part of the eye which is also called the yellow spot.

14 Function - It is used for activities that need fine vision like reading and writing. 1.3.2 Functions of Human Eye Basic function of the eye is to visualize world around us. It includes: 1. Optic system projecting an image; 2. System that perceives and encodes the received information for the brain; 3. Life-supporting' servicing system. How does the Human Eye Work? In a number of ways, the human eye works much like a digital camera: 1. Light is focused primarily by the cornea — the clear front surface of the eye, which acts like a camera lens. 2. The iris of the eye functions like the diaphragm of a camera, controlling the amount of light reaching the back of the eye by automatically adjusting the size of the pupil (aperture). 3. The eye's crystalline lens is located directly behind the pupil and further focuses light. Through a process called accommodation, this lens helps the eye automatically focus on near and approaching objects, like an autofocus camera lens. 4. Light focused by the cornea and crystalline lens (and limited by the iris and pupil) then reaches the retina — the light-sensitive inner lining of the back of the eye. The retina acts like an electronic image sensor of a digital camera, converting optical images into electronic signals. The optic nerve then transmits these signals to the visual cortex — the part of the brain that controls our sense of sight. 1.4 Vision Development and Process of Seeing 1.4.1 Normal Vision Development At birth, baby sees only in black and white and shades of gray. Nerve cells in their retina and brain that control vision are not fully developed. Also, a newborn infant's eyes don't have the ability to accommodate (focus on near objects). If baby doesn't seem to be "focusing" on objects, including mother's face. It just takes time. Despite these visual limitations, studies show that within a few days after birth, infants prefer looking at an image of their mother's face to that of a stranger. Researchers believe this

15 preference depends on large, high-contrast stimuli, like the boundary of the mother's hairline to her face. (In studies, if these boundaries were masked with a scarf or bathing cap, the infants' preference of looking at their mother's face went away). One thing anybody may notice about newborn baby is how large their eyes are. This is because that normal infant development proceeds from the head down. At birth, baby's eyes are almost 65 percent of their adult size. Vision Development in Babies Babies' vision goes through many changes in the first months after birth. Baby's eyes are not very sensitive to light in the first month of life. In fact, the amount of light required for a 1-month-old infant to be aware that light is present (called the light detection threshold) is 50 times higher than that of an adult. Infants start to develop the ability to see in colours very quickly. At one week after birth, they can see red, orange, yellow and green. But it takes a little longer for them to be able to see blue and violet This is because blue light has shorter wavelengths, and fewer colour receptors exist in the human retina for blue light. Many advances in vision development take place in months two and three. Infants develop sharper visual acuity during this period, and their eyes are beginning to move better as a team. The child should follow moving objects at this stage and starting to reach for things s/he sees. Also, infants at this stage of development learn how to shift their gaze from one object to another without having to move their head. And their eyes are becoming more sensitive to light; a 3 months old infant's light detection threshold is about 10 times that of an adult. Focus and Tracking: Newborn babies have peripheral vision (the ability to see to the sides) and in the first weeks of life gradually develop the ability to focus on an object or point in front of them. At one month, a baby can focus briefly on objects up to three feet away. By two months, infants are also able to track (follow) moving objects, as their visual coordination and depth perception improve. By three months they also have the hand/ arm control needed to bat at nearby moving objects. If a baby's eyes are not working together to focus and track objects by three months of age, a paediatrician should be consulted. Distance vision continues to develop in the early months. By four months a baby may smile when they see a parent across a room, and they can see objects outside when looking through a window.

16 Light and Images: At birth, babies are very sensitive to bright light, so their pupils remain constricted to limit the light coming into the eyes. After about two weeks, the pupils begin to enlarge and babies can see a range of shades of light and dark. As the retinas (the light-sensitive tissue inside the eye) develop, the ability to see and recognize patterns improves. High contrast images like black-and-white pictures, bull's eyes or very simple face shapes are most likely to attract babies' attention in the early weeks. The human face is always babies' favourite image. When someone holds a baby, he or she will look intently at the person's face, especially the eyes. As the baby's visual span increases in the first month, he/she will be able to see the person's whole face and will be much more responsive to facial expressions.

Colour Vision: Babies' colour vision matures at about the same rate as the other visual abilities. At one month, they are sensitive to the brightness or intensity of colour and will look longer at bold colours and contrasting patterns than at lighter tones. By about four months babies can differentiate and respond to the full range and shades of colours. To help or stimulate a 2 to 3-month-old child's vision development, the American Optometric Association (ADA) has the following recommendations: ●●●● Add new items to their room or frequently change the location of their crib or existing items in the room. ●●●● Talk to the baby as you walk around the room. ●●●● Keep a night light on to provide visual stimulation when they are awake. ●●●● While infants should be placed on their backs for sleep to decrease the risk of sudden infant death syndrome (SIDS), put them on their stomachs when they are awake and you can supervise them. This provides important visual and motor experiences. Vision Development in Preschool and School-aged Children: The child is now mobile, crawling about and covering more distance than you could ever have imagined. S/He is better at judging distances and more accurate at grasping and throwing objects. This is an important developmental period for the child. At this stage, infants are developing a better awareness of their overall body and are learning how to coordinate

17 their vision with their body movements. Focusing, tracking, depth perception, and other aspects of vision continue to develop throughout early and middle childhood, Convergence, the ability of both eyes to focus on an object simultaneously, becomes more fully developed by about age seven; this is one reason any problems a child has with focusing or eye alignment should be treated before that age. Most children are naturally somewhat farsighted (hyperopic) but can see well at other distances. More pronounced myopia (nearsightedness) and astigmatism are thought to be inherited. There is some evidence from recent studies in the United States and Australia that the amount of time school-aged children spend outdoors, in natural light, may have some impact on whether they develop mild myopia. To stimulate the development of child's eye-hand-body coordination, get down on the floor with him and encourage him to crawl to objects. Place a favourite toy on the floor just out of his reach and encourage him to get it. Also provide plenty of objects and toys that she can take apart and put together.

1.4.2 Process of Seeing The physical components of the human

visual system include the eye, the visual centre in the brain, and the optic nerve which connects the eye to the visual centre. The light rays passing from the environment to the eye through the cornea. The cornea is the external covering of the eye and in the presence of light it reflects visual stimuli. These reflect light rays passed through the pupil which is an opening in the iris. The pupil regulates the amount of light entering the eye. The lens focuses the light rays by changing their direction so that they strike the retina directly. As in a camera lens, the lens of the eye reverses the image. The retina consists of light sensitive cells namely rods and cones that transmit the image to the brain through optic nerves. Images

form in

SEVI-31 with glossary for alignment.docx (D127037367)

the retina upside down until they are flipped over the visual centre of the brain as the brain interprets the images.

Both the eyes have slightly different fields of vision since they are separated by the nose. Each of these visual fields are divided into the right and leftside. Each individual eye takes in different information, due to the different visual fields. Signals from the left visual fields of both eyes are sent to the right visual cortex and vice-versa. The information received at one eye is incomplete since only one part of the image is available. Therefore, both eyes immediately send their information to the brain, so that the

18 information can be combined. Along the way at the optic chiasma, some of the nerves from each optic nerve cross over, so that information from the left visual fields comes together and the same goes for the right visual field. The optic nerve is essentially made up of a bundle of nerve fibres that carry electrical impulses down to minute cables. After reaching the optic chiasma, another swapping of information takes place at the cell station or the geniculate body. This connection functions in accordance with the reflexes of the pupils. From here, the nerve spread out on their respective sides around the temporal part of the brain. Finally, they pass through the main exchange reaching the visual cortex. The images are interpreted at this point. How does the eye see ? For people with normally functioning eyes, the following sequence takes place: 1. Light reflects off the object we are looking at. 2. Light rays enter the eye through the cornea at the front of the eye. 3. The light passes through a watery fluid (aqueous humor), and enters the pupil to reach the lens. 4. The lens can change in thickness to bend the light, which will focus it onto the retina at the back of the eye. 5. On the way to the retina, the light passes through a thick, clear fluid called a vitreous humor. The vitreous humor fills the eyeball and helps maintain its round shape. 6. The light then reaches the back of the eye and hits

43%

MATCHING BLOCK 11/112

W

the retina. The retina translates the light into electrical impulses which are then carried to the brain by the optic nerve. 7. Finally, the

visual cortex of the brain interprets these impulses as what we see. 1.5 Principles of Refraction and Refractive Error 1.5.1 Principles of Refraction

100% MATCHING BLOCK 13/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

Refraction is the bending of light as it passes between materials of different optical density. If there is irregular bending of light due to error in medium of reflection, this becomes refractive error. 19

The purpose of the eye-ball is to receive light from the outside world and transmit it to the brain for processing. There are three aspects to this function. In the first instance, the light rays have to be correctly focused on to the back of the eye. Secondly, the light- sensation related information has to be converted to electrochemical signals by the cells within the retina. Finally, that electromechanical signal is to be transmitted to the brain through the optic nerve.

93% MATCHING BLOCK 14/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

Refraction of Eye Refraction refers to the state of focus of the eye. It is the ability of the eye to bend light so that an image is focused on the retina. So, refraction is the deflection of light from a straight path through the eye by various ocular tissues, including the cornea, lens, aqueous humour, and vitreous body. 1.5.2 Concept of Refractive Error Error in refractive media, the eye gets unclear or blurring image. When there is a deviation in light rays from a distant object brought to a focus on the retina, the image that is formed on the retina appears blurred.

The variation in image formation

96% MATCHING BLOCK 16/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

is known as ametropia in which parallel rays are not accurately focused on the retina. Ametropia includes hypermetropia, myopia and astigmatism. Therefore, refractive error is defined as "a defect in the eye that prevents light rays from being brought to a single focus exactly on the retina" (Bourgeault, 1969).

The principles of refractive errors are: 1. Corneal curvature, 2. Depth of the anterior chamber, 3. Shape of the lens, 4. Length of the eye (axial length). These four elements change over time as the eye grows (e.g., axial length) and matures in later years (e.g., quality of tears which affects the air-tear interface). The emmetropic eye is able to achieve a perfect focus. Ametropia is the global term referring to any refractive error. Refractive development is influenced by both the environmental and genetic factors. Significance of Refractive Errors • Refractive errors are important because they account for half the cases of avoidable vision impairment globally (153 million people). • Undetected refractive errors in childhood may lead to behavioural problems and adversely affect social interaction and performance (academic or sporting) at school.

20 • It has been found that a minor reduction in vision has been associated with an increased risk of death and physical-social-emotional problems in people aged over 50 years. • Under-corrected refractive error may account for up to 75% of all vision impairment in the third-world countries. Interventions to treat refractive errors (e.g., spectacles) are simple and cost-effective. However, global estimates indicate that more than 2.3 billion people in the world experience poor vision due to refractive error of which 670 million people are considered visually impaired because they do not have access to corrective treatment. Types of Refractive Error There are different types eye-problems due to refractive errors in the eyes. Some of these are given below: 1. Myopia: As the normal eye is virtually round, the rays of light coming from outside, touch the retina. The myopic eye is longer from the front to the back and the extra length prevents the image being in sharp focus. Actually, in myopia, the eyes are too deep and cornea is too curving which are the main causes of myopia. There are mainly three types of myopia: i. Congenital Myopia • Present at birth, • May be unilateral as well as bilateral, • Bilateral myopia may be associated with squint. ii. Simple Myopia • Most common type of myopia, • Does not progress after adolescence. iii. Pathological Myopia • Type of progressive and degenerative myopia, • Begins at the age of 5-10 years, • Strongly hereditary,

21 • Common in women, Jews and Japanese. Symptoms of Myopia: • Black spots are seen floating before the eyes, • Discomfort in performing near work, • Flashes of light may be seen, • Indistinct distant vision is the most common symptom. Usually the young children are unable to see clearly. Treatment of Myopia: • It is treated by prescribing suitable corrected concave lens for concave use. In high myopia, spectacles should be made to fit closely to the eye. 2.

Hypermetropia This is opposite to myopia. Short length of eye ball is the cause of it. It may also consist of flat curvature of cornea. Newborns are invariably hypermetropic. The incidence decreases rapidly with age remaining at about 50% after 20 years. Symptoms of Hypermetropia • Blurring of vision for near work, • Frontal headache and eye strain, • Burning and dryness in the eye. Treatment of Hypermetropia • It is treated by prescribing suitable correcting spherical convex lenses. 3. Astigmatism It is that condition of refraction in which a point of light cannot be made to produce a punctuate image upon the spherical retina. It is due to unequal curvature of cornea and decentring of lens. Regular Astigmatism Normally cornea is flatter from side to side (horizontal meridian) perhaps because of the pressure of the eyelids. It is curved above downwards (vertical). Regular astigmatism is present when the two principal meridians are at the right angles. It can be corrected by lenses.

22 • According to the rule - the vertical meridian is more curved, e.g., as in normal cornea. • Against the rule - the horizontal meridian is more curved, e.g., as after cataract surgery. • It is present when the corneal surface is irregular. It cannot be adequately corrected by lens, e.g., as following healed corneal ulcer. In that case, Soft Contact lens may be used. Symptoms of Regular Astigmatism; • Diminished visual acuity is the most troublesome clinical symptom; • Eye strain and headache after short time of near work is usually present; • The letters in the book appear to be 'running together'. Treatments of Regular Astigmatism • When there are symptoms, suitable cylindrical lenses are prescribed for constant use. 1.6 Concept and Definitions of Blindness and Low Vision Visual impairment describes vision that cannot be fully corrected by ordinary prescription lenses, medical treatment, or surgery. The term visual impairment includes conditions ranging from the presence of good usable vision, low vision, or to the absence of any sight at all-total blindness. Many terms are used when people refer to visual impairment. These terms are explained below: 1.6.1 Blindness

The term blindness means no light perception of both the eyes of a human being. Probably the best way to describe this is not to stand in a dark place or cover your eyes, but rather think about what you can see directly behind you. Now, do not turn your head, but use your eyes to see directly behind you. That may utter sense of darkness where only other senses describe what is behind you is the closest to no light perception a sighted individual may see. Even if you close your eyes and stand with a blind fold in utter darkness, your eyes still try to perceive some form of imagery. Blindness with light perception has several different forms. However, people often see light with shadows or shadows with some light. The way one sees in this state depends on the condition of the eye and the cause for the sight loss.

23 Legal blindness refers to a term developed to determine cut off assessments for sight loss. It refers to a visual acuity on a Snellen's Chart of 20/ 200 corrected with best eye. This means that the size of a sign of a normally sighted person sees at 200 feet, a legally blind individual must be 20 feet away. A second classification for legal blindness involves tunnel vision. In this case, a person must have a field of view less than 20 degrees while looking forward. Definition of Blindness :

Simple Definition: Inability of a person to count fingers from a distance of 6 meters or 20 feet. Technical Definition: Vision of 6/ 60 or less with the best possible spectacle correction and Diminution of field vision to 20° or less in better eye. ●●●● Severe Visual Impairment Severe visual impairment is a term used by researchers at the National Center for Health Statistics (NCHS) to describe visual impairment in people who are unable to read ordinary newsprint even with correction. This term, used primarily for studying visual impairment in the population, is not used in clinical references by eye care professionals. People with a severe visual impairment may or may not be legally blind. ●●●● Visually Impaired

The term visually impaired, also used by the National Center for Health Statistics for studying visual impairment in the population, describes visual impairment in people who have difficulty reading ordinary newsprint even with correction. Like the term severe visual impairment, visual impairment is used by researchers who study the population, and is not used in clinical references. ●●●● Presbyopia Presbyopia refers to the eye's loss of accommodation, the eye's focusing power and ability to adjust the focus of the eye on the distance between the individual and the object People with presbyopia, typically those age 40 and older, experience a progressive inability to focus for near vision viewing as the lens becomes less elastic with age. Lenses with magnification are used to provide the correction needed. These lenses are commonly referred to as "reading glasses," or necessary magnification can be added to a person's regular eyeglasses as bifocals, or trifocals. Variable focus lenses are also available to correct presbyopia.

Variable focus lenses are also available to correct presbyopia.

24 1.6.2 Low Vision Low vision is a reduced level of vision that cannot be fully corrected with conventional glasses. It is not the same as blindness. Unlike a person who is blind, a person with low vision has some useful sight. However, low vision usually

64% MATCHING BLOCK 15/112

W

interferes with the performance of daily activities, such as reading or driving. A person with low vision

may not recognize images at a distance or be able to differentiate colours of similar tones. One is legally blind when the best corrected central acuity is less than 20/ 200 (perfect visual acuity is 20/ 20)

58% MATCHING BLOCK 17/112

W

in the better eye, or the side vision is narrowed to 20 degrees or less in the better eye.

People who are legally blind may still have some useful vision. It may be noted that if anybody is legally blind, s/he may qualify for certain government benefits. Furthermore, It is estimated that approximately 17 percent of normal people over the age of 65 years are either blind or have low vision. Symptoms of Low Vision: • Difficulty in recognizing objects at a distance (viz., street signs or bus signs) • Difficulty in differentiating colours (particularly in the green-blue-violet range) • Difficulty in seeing well up close (viz., reading or cooking) The symptoms described above may not necessarily mean that anybody has the low vision. However, if you experience one or more of these symptoms, contact the eye doctor for a complete examination. The specialist eye doctor can tell the difference between normal changes which are common with age and changes caused by eye disease. Causes of Low Vision: Although low vision can occur at any stage in life, it primarily affects the elderly, but it is not a natural part of aging. Although most people experience some physiological changes with age (presbyopia), these changes usually do not lead to low vision. Most people develop low vision because of eye diseases. Common causes of low vision, particularly with older adults, include muscular degeneration, glaucoma, and diabetic retinopathy. When vision impairment is recognized early, treatment can be more effective, enabling people to maintain as much independence as possible. Low Vision Aids: Many types of assistive devices are available to help people with low vision. These items include special glasses and other magnification devices and large print reading materials. Other communication aids include computer software and various other technological devices.

Concept of Visual Acuity, Visual Field, Depth Perception and Contrast Sensitivity 1.7.1 Visual Acuity

92% MATCHING BLOCK 19/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

Visual acuity (VA) commonly refers to the clarity of vision. Visual Acuity is dependent on some optical and neural factors, i.e., (i) the sharpness of the retinal focus within the eye, (ii) the health and functioning of the retina, and (iii) the sensitivity of the interpretative faculty of the brain. Visual acuity is

a measure of our centra! vision, the ability to distinguish details and shapes of objects. Distant vision is tested with a chart with differently sized letters read from a distance of six metres away. This is called the Snellen's Test Types.

84%

MATCHING BLOCK 20/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

Visual acuity is typically measured while fixating, i.e. as a measure of central (orfoveal) vision, for the reason that it is highest there. However, acuity in peripheral vision can be of equal (or sometimes higher) importance in everyday life. Acuity declines towards the periphery in an inverse-linear (i.e. hyperbolic) fashion. Visual acuity is a measure of

the spatial resolution of the visual processing system. As it is sometimes referred to by optical professionals, visual acuity of a person is tested to identify so-called optotypes - stylized letters, Landolt rings, Le symbols, or other patterns - on a printed chart (or some other means) from a set viewing at a fixed distance. Optotypes are represented as black symbols against a white background (i.e. at maximum contrast). The distance between the person's eyes and the testing chart is set so as to approximate optical infinity in the way the lens attempts to focus (far acuity), or at a defined reading distance (near acuity). Normal visual acuity is commonly referred to as 20/ 20 vision, the metric equivalent of which is 6/ 6 vision. At 20 feet or 6 meters, a human eye with nominal performance is able to separate contours that are approximately 1.75 mm apart. Vision of 20/ 40 corresponds to lower than nominal performance and vision of 20/10 corresponds to better performance. Acuity is a measure of visual performance and does not directly relate to the eyeglass prescription required to correct vision. Instead, an eye examination seeks to find the prescription that will provide the best corrected visual performance achievable. The resulting acuity may be greater or less than 20/ 20 = 1.0. Indeed, a subject diagnosed as having 20/ 20 vision will often actually have higher visual acuity because, once this standard is attained, the subject is considered to have normal (in the sense of undisturbed)

26 vision and smaller optotypes are not tested. Emmetropic subjects with 20/ 20 vision or 'better' (20/ 15, 20/ 10, ect), may still require an eyeglass correction for other problems related to the visual system, such as eye strain ocular injuries. Measurement: Visual acuity is measured by a psychophysical procedure and as such relates the physical characteristics of a stimulus to a subject's percept and her/ his resulting responses. Measurement can be made by using an eye chart, by optical instruments, or by computerized tests like the 'FrACT. Care must be taken that viewing conditions correspond to the standard, such as correct illumination of the room and the eye chart, correct viewing distance, enough time for responding, error allowance, and so forth. In the European countries, these conditions are standardized by the European norm (EN ISO 8596, previously DIN 58220). 1.7.2

SEVI-31 with glossary for alignment.docx (D127037367)

Visual Field The visual field refers to the total area in which objects can be seen in the side (peripheral) vision while you focus your eyes on a central point. The

visual field is the "spatial array of visual sensations available to observation in introspectionist psychological experiments." The equivalent concept for optical instruments and sensors is the 'field of view' (FOV). In optometry and ophthalmology a visual field test

98%

MATCHING BLOCK 22/112

SA

TFG AMARA NAHEED (0-JL).docx (D124054780)

is used to determine whether the visual field is affected by diseases that cause local scotoma a more extensive loss of vision or a reduction

in sensitivity (increase in threshold). Normal limits : The normal human visual field extends to approximately 60 degrees nasally (toward the nose, or inward) from the vertical meridian in each eye, to 100 degrees temporal (away from the nose, or outwards) from the vertical meridian, and approximately 60 degrees above and 75 below the horizontal meridian. In the United Kingdoms, the minimum field requirement for driving is 60 degrees either side of the vertical meridian, and 20 degrees above and below horizontal. The macula corresponds to the central 13 degrees of the visual field; the fovea to the central 3 degrees. Measuring the Visual Field: The visual field is measured by perimetry. This may be kinetic, where points of light are moved inwards until the observer sees them, or static, where points of light are

27 flashed onto a white screen and the observer is asked to press a button if s/he sees it. The most common perimeter used is the automated Humphrey Field Analyzer and Heidelberg Edge Perimeter. Another method is to use a campimeter, a small device designed to measure the visual field. Patterns testing the central 24 degrees or 30 degrees of the visual field, are most commonly used. Most perimeters are also capable of testing the full field of vision. Another method is for the practitioner to hold up 1, 2, or 5 fingers in the four quadrants and center of a patient's visual field (with the other eye covered), if the patient is able to report the number of fingers properly as compared with the visual field of the practitioner, the normal result is recorded as 'full to finger counting' (often abbreviated FTFC). The blind spot can also be assessed via holding a small red object between the practitioner and the patient. By comparing when the red object disappears for the practitioner, a patient's abnormally large blind spot can be identified. There are many variants of this type of examination (e.g., wiggling fingers at visual periphery in cardinal axes).

77%

MATCHING BLOCK 23/112

SA

TFG AMARA NAHEED (0-JL).docx (D124054780)

Visual Field Loss: Visual field loss may occur due to disease or disorders of the eye, optic nerve, or brain.

Classically, there are four types of visual field defects: i. Altitudinal field defects, loss of vision above or below the horizontal - associated with ocular abnormalities; ii. Bitemporal hemianopia, loss of vision at the sides; iii. Central scotoma, loss of central vision Homonymous hemianopia, loss at one side in both eyes - defect behind optic chiasm (see below); In humans, confrontational testing and other forms of perimetry are used to detect and measure visual field loss. Different neurological difficulties cause characteristic forms of visual disturbances, including hemianopsias (shown below without macula sparing), quadrantanopsia, and others. 1.7.3

100%

MATCHING BLOCK 24/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

Depth Perception Depth perception is the visual ability to perceive the world in three dimensions (3

D) and the distance of an object. Depth perception arises from a variety of depth cues. These are typically classified into binocular cues that are based on the receipt of sensory information in three dimensions from both eyes and monocular cues that can be represented in just two dimensions and observed with just one eye. Binocular cues include stereopsis, eye convergence, disparity, and yielding depth from binocular vision through exploitation of parallax. Monocular cues include size: distant objects subtend smaller visual angles than near objects, grain, size, and motion parallax. Disorders Affecting Depth Perception: i. Ocular conditions such as amblyopia, optic nerve hypoplasia, and strabismus may reduce the perception of depth. ii. Since (by definition), binocular depth perception requires two functioning eyes, a person with only one functioning eye has no binocular depth perception. iii. It is typically felt that depth perception must be learned in infancy using an unconscious inference. 1.7.4

98%

MATCHING BLOCK 25/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

Contrast Sensitivity Contrast sensitivity is a very important measure of visual function, especially in situations of low light, fog or glare, when the contrast between objects and their background is

97%

MATCHING BLOCK 26/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

often reduced. Driving at night is an example of an activity that requires good contrast sensitivity for safety.

As mentioned above, contrast sensitivity describes the ability of the visual system to distinguish bright and dim components of a static image. Visual acuity can be defined as the angle with which one can resolve two points as being separate, given that the image is shown with 100% contrast and is projected onto the fovea of the retina. Thus, when an optometrist or ophthalmologist assesses a patient's visual acuity using a Snellen's chart or some other acuity chart, the target image is displayed at high contrast (e.g., black letters on a white background). A subsequent contrast sensitivity exam may demonstrate difficulty with decreased contrast (e.g., grey letters on a white background). To assess a patient's contrast sensitivity, one of several diagnostic examinations may be used. Most charts in an ophthalmologist's or optometrist's office will show images of varying contrast and spatial frequency. Parallel bars of varying width and contrast, known as 'sine-wave gratings', are sequentially viewed by the patient. The width of the bars and their distance apart represent spatial frequency, measured in cycles per degree. Studies have demonstrated that medium-level spatial frequency, approximately 5-7 cycles per degree, is optimally detected by most individuals, compared with low or high-level spatial frequencies. The contrast threshold can be defined as the minimum contrast that can be resolved by the patient. The contrast sensitivity is equal to $1 / \text{contrast-threshold}$. Using the results of a contrast sensitivity exam, a contrast sensitivity curve can be plotted, with spatial frequency on the horizontal, and contrast threshold on the vertical axis. Also known as contrast sensitivity function (CSF), the plot demonstrates the normal range of contrast sensitivity, and will indicate diminished contrast sensitivity in patients who fall below the normal curve. Some graphs contain "contrast sensitivity acuity equivalents", with lower acuity values falling in the area under the curve. In patients with normal visual acuity and concomitant reduced contrast sensitivity, the area under the curve serves as a graphical representation of the visual deficit. It can be because of this impairment in contrast sensitivity that patients have difficulty driving at night, climbing stairs and other activities of daily living in which contrast is reduced. The graph demonstrates the relationship between contrast sensitivity and spatial frequency. The target-like images are representative of center-surround organization of neurons, with peripheral inhibition at low, intermediate and high spatial frequencies. Used with permission from Brian Wandell, PhD. Recent studies have demonstrated that intermediate-frequency sinusoidal patterns are optimally-detected by the retina due to the center-surround arrangement of neuronal receptive fields. In an intermediate spatial frequency, the peak (brighter bars) of the pattern is detected by the center of the receptive field, while the troughs (darker bars) are detected by the inhibitory periphery of the receptive field. For this reason, low- and high-spatial frequencies elicit excitatory and inhibitory impulses by overlapping frequency peaks and troughs in the center and periphery of the neuronal receptive field. Other environmental, physiologic and anatomical factors influence the neuronal transmission of sinusoidal patterns, including adaptation. Decreased contrast sensitivity arises from multiple etiologies, including retinal disorders such as Age-Related Macular Degeneration (ARMD), amblyopia, lens abnormalities, such as cataract, and by higher-order neural dysfunction, including stroke and Alzheimer's disease. In light of the multitude of etiologies leading to decreased contrast sensitivity, contrast sensitivity tests are useful in the characterization and monitoring of dysfunction, and less helpful in detection of disease.

..... 1.9 Let us sum up Our eye is one of the most complex sense organs of the body. It helps us to see & interpret the shapes, colours & dimensions of the objective world. While cruesing into the lesson, we ventured through the sophisticated structure of an eye, its components, viz, sclera, conjunctiva, cornea, pupil, anterior chamber, lens, retina, vitreous body & optic nerves and their respective functions. All these structural components functions to visualize world around us. The human eye works much like a digital camera. At birth, babies are very sensitive to bright light & thus light coming to the eyes is limited. Babies vision goes through many changes. Vision development during the preschool & school-aged children are based on few parameters like-focusing, tracking, depth perception & other aspects of vision. All these functionaries follows certain principles of refraction & refractive error. There are different types of eye-sight problems like myopia, hypermetropea, astigmatism etc. All these problems are the result of certain refractive errors in the eyes. There are treatments available for such kinds of eye problems. Another pertinent issue concerning eye & vision is the concept of blindness & low vision. Visual impairment describes vision that cannot be fully corrected by ordinary prescription. There are different types of visual impairment, some are manageable while others are not. Many types of assistive devices are available to help people with low vision.

∅

100%	MATCHING BLOCK 34/112	W	
The visual acuity for distance is measured as the maximum distance at which person can see a certain object, divided by the maximum distance at which a person with normal			

eye sight can see the same. Thus a visual acuity 6/60 meter means that the person examined cannot see properly at a distance of 6 meters the object, which a person with normal eye sight would be able to see at 60 meters or, visual acuity of 20/200 means that what a normal person can see at a distance of 200 feet a visually impaired child can not see it properly at a distance of 20 feet. 2.3.1 Loss of visual acuity: ∅ Loss of visual acuity means inability to discriminate high contrast and unable to find detail at a distance. ∅ Lack of clarity and sharpness of vision. 2.3.2 Estimation of percentage of visual loss: (Using best correcting spectacle lens). For purpose of calculating visual acuity loss, distance vision and near vision are equally weighted. Distance (Snellen) vision Near vision Visual acuity Percentage Loss Jaeger Test Type Percentage Loss English Metric 20/20 6/6 0 1 0 20/30 6/9 5 2 0 20/40 6/12 15 3 10 20/50 6/15 25 6 50 20/80 6/20 40 7 60 20/100 6/30 50 11 85 20/200 6/60 80 13 90 Example: If the distance acuity is 20/80 and the subject can read Jaeger 6. Loss of visual acuity= $40+50/2=45\%$ Therefore Visual acuity efficiency= 55% Loss of visual acuity= $40+50/2=45\%$ Therefore Visual acuity efficiency= 55%

38 2.4 Visual Field : Visual field is generally 180 degrees in a normal eye Normal fields in each eye can approximately see 60degrees to the nasal side by fixing on a centre point, 90 degree to the temporal side, 50 degree to the superior side that is up the centre and 70 degree inferior side that is down. This is peripheral field. Restrictions in the normal fields of vision may lead the child seeing only small portion of the environment at a time. It is like figuring out the entire puzzle from one piece. The child may not be able to see the objects on the left side or right side or in the centre. These restrictions in the field can be classified in the following way: Mildfield restrictions: This means loss of peripheral vision and 20-40 degree of central field remains. Not very restricting but mobility problems may be there. Moderate field restrictions: Central field is 10-20 degree or less. Some special consideration has to be given and the aids are to be prescribed. Severe field restriction: When central field is just 10 degrees or less. The field of vision may have restrictions in the central field while the child's peripheral vision may remain.

39 2.4.1 Loss of Visual Field: Definition: Loss of visual field means that the field of vision is very much limited or restricted and hence the area which can be seen without shifting eye gaze is narrowed down to a specific limit. The commonly used tests for assessing field of vision are Lister's perimeter and Bjerrum's screen. A white test object is used in eight meridians as given below. This can be done with a 3mm object at 1/3 metre using a perimeter. Directions Range of minimal Moderate visual Severe visual normal Visual Field field field Temporally 85degrees 60 degrees 30 degrees Down and temporally 85 degrees 40 degrees 30 degrees Down 65 degrees 40 degrees 30 degrees Down and Nasally 50 degrees 30 degrees 20 degrees Nasally 60 degrees 40 degrees 30 degrees Up and Nasally 55 degrees 40 degrees 30 degrees Up 45 degrees 30 degrees 20 degrees Up and Temporally 55 degrees 40 degrees 30 degrees Total 500 degrees 320 degrees 220 degrees Calculation: Visual field = $320 \times 100 / 500 = 64\%$ Moderate Loss of visual field = $100 - 64 = 36\%$ Visual field = $220 \times 100 / 500 = 44\%$ Severe Loss of visual field = $100 - 44 = 56\%$ Therefore, loss of visual field means that the field of vision is very much restricted or limited. Peripheral field loss: loss of peripheral vision causes a restricted field of vision. Objects in the centre remain visible. The causes of peripheral field loss include glaucoma and retinitis pigmentosa.

40 2.5 Colour Vision Defect: Colour vision defects are present in the community with a greater percentage of boys than girls affected. Red-green problems are the most common. The hereditary colour vision problems are present in the visual impaired persons but these are also some eye conditions that affect colour vision. Colour vision and fine detail are processed by the central part of the retina and any condition affecting this area can cause a colour vision defect. There is a small percentage of students who have no colour vision and see everything in shades of grey similar to image on a black and white television. If a colour vision defect is present care should be taken not to use colour cues or direction and when presenting work on the board, some colour will not be seen against the green surface.

2.5.1 Loss of contrast sensitivity: Due to loss of visual acuity and field of vision, the sensitivity of the optic nerve is not actively interpreted with faculty of the brain. In that case, the relative difference between lightness and darkness of things is not observed clearly.

2.5.2 Role of teacher for low vision children: The teacher can increase the amount of information available to a student by maximizing contrast. Sharp contrast between an object and its background makes the object more visible to the students. This is essential in reading, writing, drawing, cutting, pasting and physical education- Ø Black and white or black and yellow provide the best contrast. Intense blue, green or purple on a buff or light yellow background may be preferable if glare is a problem. The student prefers experiment with the colour of paper. Ø Keep the chalkboard as clean as possible. The student may have a preference for yellow or white chalk. Large chalk can be purchased. A white board provides good contrast if glare can be eliminated and a dark marker is used. Ø Reduce visual distractions around an object. Ø Avoid using materials with confusing patterns. Bold, sharp print provides good contrast. When enlarging print copies, try to achieve clear, non-blurry copies.

41 2.6 Refractive Errors and Common Eye Diseases 2.6.1. Refractive Errors

94%

MATCHING BLOCK 36/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

Refractive Error is defined as a defect in the eye that prevents light rays from being brought to a single focus exactly on the retina" (Bourgeault.

S.E .. 1969). Numerous variables influence upon refraction, e.g. corneal curvature, depth of the anterior chamber, shape of the lens, and length of the eye. Upon entering the eye a ray of light passes through the cornea, the aqueous humour the anterior and posterior surfaces of the lens, and the vitreous to focus upon the retina's fovea. The refractive power of the eye is determined by the radius of curvature of the cornea and the lens as well as the refractive index of the aqueous and the vitreous. This power can change during life with growth, age, or changes in health or exposure to certain drugs or chemicals. A normal physiological alteration in the ability of the lens to change its convexity occurs at a predictable rate from childhood to a later adult life. The lens of the child is very flexible and can readily change its curvature enabling the eye to focus on a very near object as well as a more distant object. As the age of the lens increases, it grows in thickness and is less able to change its curvature. When it loses most of the adjusting mechanism or accommodation, it is termed as presbyopia. 1. Myopia This is the condition

in which the eye is too long and the light is focused in front of the retina.

Distant objects are blurred but the near objects are seen clearly. The eye has too much optical power and to correct it the optical power is reduced by either minus glasses or contact lenses, or by surgery. Description - myopic eyes have too much optical power and so focus the image in front of the retina. This arises as a result of the physiological variation in the length of the eye or an excessively curved cornea. This common condition affects about 1 in 4 adults in the UK and tends to manifest itself in adolescence or early adulthood. It is said to be mild (up to 3.0 D), moderate (3.0-6.0 D) or severe/high- degree 3.0-6.0 D). The latter affects about 200,000 British people and can be associated with degenerative fundal changes (Forster-Fuchssspots). It is also associated with an increased risk of retinal detachment, cataract formation and glaucoma.

42 1. Congenital or developmental ●●●●● Child born with elongated eyes ●●●●● Refraction may be up to -10.0D ●●●●● Typical fundus changes are seen ●●●●● Progress is rare. 1 Myopia : ●●●●● Commonest clinical type ●●●●● Not progress much after the adolescence. ●●●●● May be up to -5D, or -6D. ●●●●● No degenerative changes are seen in the fundus ●●●●● Associated with good vision and good prognosis. 2 Hypermetropia (hyperopia) This is the condition in which the eye is too short and the light is focused behind the retina. The eye has less optical power than is needed. When young the eye can use the lens within the eye to compensate, but reading glasses are needed at a relatively early age. Later, distance glasses (plus) are needed as well, such that glasses for distance and near are required. Description - this is the opposite problem to myopia. In this case, the eye does not possess enough optical power for its refractive length and therefore an object is focused behind the retina, so giving rise to a blurred image. Mild hypermetropia is a common finding in babies and very young children and this usually resolves by about 3 years of age. Persistent hypermetropia is associated with an increased risk of glaucoma, squint and amblyopia. ●●●●● Physiological in almost all new-borns due to shortness of their globes (approx.+2.5D). ●●●●● Pathological: when the retina displaced forward (as in retinal detachment, CSR, orbital tumors and etc..) ●●●●● In microphthalmos or nanophthalmos - where the axial length is less than 20.mm

43 Symptoms: According to the amount of hypermetropia and the age of the patient. 1. Blurred vision - more for near than for distance 3. Eye strain (accommodative asthenopia) 4. Convergent squint - due to continuous effort of accommodation Excess of convergence dissociation of muscle balance convergent squint. 4. Early onset of presbyopia. 3. Astigmatism This is the condition where the eye does not focus the light evenly, usually due to the cornea of the eye being more curved in one direction than the other. It may occur on its own or may be associated with myopia or hypermetropia. Description - not only do light rays have to focus at the level of the retina (as opposed to in front or behind it) but also on a single point. This is achieved through the symmetry of the corneal and lens curvatures around their circumference. In astigmatism, variations in the symmetry of these curvatures (usually corneal) result in rays failing to focus on a single point. The degree of astigmatism is measured in cylinders (cyl). Astigmatism is often present in association with some degree of myopia or hypermetropia. A mild degree of astigmatism is relatively common in childhood and resolves in a number of cases. More severe astigmatism may lead to amblyopia, especially if there is an associated squint. Causes ●●●●● Previous eye surgery ●●●●● Previous corneal injury ●●●●● Corneal dystrophies ●●●●● Congenital cataract ●●●●● Optic nerve hypoplasia ●●●●● Retinitis pigmentosa

44 4. Presbyopia Presbyopia is a condition that occurs as a part of normal aging and is not considered to be an eye disease. The process occurs gradually over a number of years. Symptoms are usually noticeable by age 40-45 and continue to develop until the process stabilizes some 10-20 years later. Presbyopia occurs without regard to other eye conditions. Causes and symptoms In the eye, the crystalline lens is located just behind the iris and the pupil. Tiny ciliary muscles pull and push the lens, adjusting its curvature, and thereby adjusting the eye's focal power to bring objects into focus. As individuals age, the lens becomes less flexible and elastic, and the muscles become less powerful. Because these changes result in inadequate adjustment of the lens of the eye for various distances, objects that are close will appear blurry. The major cause of presbyopia is loss of elasticity of the lens of the eye. Loss of ciliary muscle power, however, is also believed to contribute to the problem. Symptoms of presbyopia result in the inability to focus on objects close at hand. As the lens hardens, it is unable to focus the rays of light that come from nearby objects. Individuals typically have difficulty reading small print, such as that in telephone directories and newspaper advertisements, and may need to hold reading materials at arm's length. Symptoms include headache and eyestrain when doing close work, blurry vision, and eye fatigue. Symptoms may be worse early in the morning or when individuals are fatigued. Dim lighting may also aggravate the problem.

45 2.6.2 Common Eye Diseases Albinism Lack of pigment in all parts of the body, the skin is white and the hair is pale yellow. Albinism often entails photophobia (acute sensitivity to light) Albinism children will exhibit visual effects such as reduced visual acuity for near and distance vision, astigmatism, nystagmus, very photophobic. A void glare of bright sunlight, reflected light from white or shiny surfaces, wearing tinted glasses or dark sunglasses are suggested for these children as safety measures and use of a barrier sun-cream to avoid sunburn. Amblyopia/Amblyopia Ø Amblyopia is known as lazy eye. It is a disorder of the visual system that is characterized by poor vision or indistinct vision in an eye that is otherwise physically normal or out of proportion to associated structural abnormalities. It has been estimated that 1-5% of the population are affected. The problem is that no transmission or poor transmission of the visual stimulation through the optic nerve to the brain for a sustained period of dysfunction or during early childhood thus resulting in poor vision or dim vision. Amblyopia is normally affected by one eye, but it is possible to be amblyopic in both eyes if both are similarly deprived of a good or clear visual image. Detecting the condition in early childhood increases the chance of successful treatment. Symptoms Ø Poor deep perception. Ø Poor spatial acuity. Ø Poor visual image. Ø Poor sensitivity to contrast. Ø Poor sensitivity to motion. Ø Problems of binocular vision, such as limited stereoscopic depth perception. Ø Have difficulty seeing the three dimensional images in hidden stereoscopic displays such as auto stereo grams.

46 Optic atrophy or damaged nerve fibre: Ø Complete or partial destruction of the optic nerve that causes the damaged nerve fibres of the optic disc to atrophy. The primary causes of optic atrophy are an injury to the head, retinal disease affecting the nerve itself and a lack of nourishment of the optic nerve. Optic atrophy can be congenital or acquired in later life Atrophy may be primary due to some diseases of the optic nerve itself, as in neuritis. It may be consecutive from a retinal / lesion such as degeneration of the ganglion cells, as in retinitis pigmentosa. It may also .e be the result of injury, such as a blow to the eye. The optic nerve is part of the brain and has no capacity for regeneration. Hence, there can be no recovery from optic atrophy. The range of impairment can be from moderate to total loss of vision, affecting central acuity and fields of vision and colour vision. Retinitis Pigmentosa (or) Degeneration of Retinal Tissue(RP). Ø Retinitis pigmentosa (RP) is a hereditary slow degenerative disease of the retina. The condition affects the peripheral area of retina including rod cells. It may result into night blindness, tunnel vision and inability to see in dark. Though some children are bom with poor vision, it begins in childhood. It is progressive and results into blindness in middle or advanced age. Visual acuity is often normal, the field of vision is so poor that the person falls in the category of blindness. Ø Precaution: (i) A close watch by parents & teachers to note any changes in the vision. (ii) Sympathetic & proper handling & understanding of socio-psychological & behaviour problems of the individual. (iii) Training in visual skills of scanning and reorientation. (iv) Training in orientation and mobility. (v) Genetic counselling of the individual. Ø Treatment / Management : (i) Treatment by radiation or photo coagulation. (ii) Generally surgery is necessary to remove the affected eye.

47 (iii) Genetic counselling is desirable. (iv) Avoid consanguineous marriage. Retinal Detachment Ø Retinal detachment is disorder of the eye in which the retina peels away from its underlying layer of support tissue. Initial detachment may be localized, but without rapid treatment the entire retina may detach, leading to vision loss and blindness. It is a medical emergency. The retina is a thin layer of light sensitive tissue on the back wall of the eye. The optical system of the eye focuses light on the retina much like light is focused on the film in a camera. The retina translates that focused image into neural impulses and sends them to the brain via the optic nerve. Occasionally, posterior vitreous detachment, injury or trauma to the eye or head may cause a small tear in the retina. The tear allows vitreous fluid to seep through it under the retina, and peel it away like a bubble in wallpaper. It refers to separation of retina from its pigment epithelium layer. From the clinical point of view it is divided into two classes- (a) Secondary detachment due to an obvious mechanical cause, subsequent to other happenings in the eye. (b) Simple detachment due to development of a hole in the retina. It is caused by degenerative myopia, diabetes, inherited diabetic retinopathy. It leads to painless loss of vision, appearance of flashing light, visual field loss and decreased visual activity. Symptoms Ø A flash of light (photopia). Ø A sudden dramatic increase in the number of floaters. Ø A slight feeling of heaviness in the eye. Ø A dense shadow that starts in the peripheral vision and slowly progresses towards the central vision. Ø The impression that a veil or curtain was drawn over the field of vision. Ø Central visual loss.

48 Treatment: Surgical repair should be performed as soon as possible. It is generally treated by laser surgery and cryosurgery. Nystagmus: Nystagmus is an unintentional jittery movement of the eyes. This a condition in which the natural movement of the eye is grossly exaggerated, resulting in uncontrolled eye movements and seriously affects perceptual efficiency. When nystagmus is present, it is likely to be associated with seriously defective vision. Causes: Medication and drugs can cause nystagmus. Causes include excessive drinking of alcohol or use of medications such as those given for seizure control. Diagnosis of Nystagmus Diagnosis is made clinically based on the medical history and physical examination. Treatment of Nystagmus: The reduced vision may be improved with glasses and low vision aids, if the eyes are more stable looking in a certain direction, glasses with prisms or eye muscle surgery may improve the head position and allow better vision. Vitamin-A deficiency: Vitamin-A is essential for the build the surface tissues in our body, including parts of eye. Vitamin-A deficiency may lead to corneal damage, ulceration and blindness particularly in combination with measles or malnutrition. It is also known as xerophthalmia. Keratomalacia is the severe form of xerophthalmia. Night blindness is the earliest symptom of this disease. Night blindness: Ø In this condition the subjects cannot see small objects in dim light. Ø Difficulty in reading in dim light is also experienced.

49 Xerophthalmia : Ø In this condition conjunctiva and cornea appear dry due to the keratinisation of epithelial lining. Ø The conjunctiva is dry thickened, wrinkled pigmented. Keratomalacia: Ø If xerophthalmia is not treated with vitamin-A, it develops into keratomalacia. Ø In this condition, the corneal epithelium becomes opaque, ulceration and bacterial invasion of the cornea bring about its destruction resulting in blindness. Early diagnosis and treatment will be the best way to check this defect. Due to deficiency of vitamin-A complaint from patient are poor vision, difficulty seeing in dim light, eyes become sensitive to bright light. Symptoms: Ø Thick white spots on both sides of the cornea. Ø Spots on the conjunctiva. Ø Conjunctiva becomes wrinkled. Ø Cornea erupts. Suggestions: Ø It is necessary to teach the public to eat dark green vegetables which are rich in vitamin-A. Ø This is particularly important for pregnant woman, weaning children, growing infants and adults. Corneal ulcer: The cornea is the front part of the eye through which the light ray passes prior to forming the visual image in the retina. Two groups of corneal disorders are :- 1. Inflammation of the cornea. 2. Many abnormal growths are appearing at birth or at times later in life.

50 Corneal inflammations may be divided into three types :- (a) Superficial keratitis. (b) Deep dermatitis. (c) Corneal ulcer. Causes : A foreign body is the cause for most common corneal disorders and ulcers frequently occur as complications of corneal abrasions or foreign body. When the foreign body stays in the cornea, it may lead to ulcer which in turn reduces the vision from mere blurring to total blindness. Due to indiscriminate use and abuse of antibiotics and steroids, the corneal ulcer is formed. Some specific viruses such as herpes simplex. etc. may also cause corneal ulcer. Precaution: The eyes should be washed with clean water when the foreign body stays in the eye and on any account the eye should not be rubbed. Trachoma:

100%

MATCHING BLOCK 38/112

SA

DEPP 326 1st.docx (D90532091)

Trachoma is a chronic contagious disease of the conjunctiva and cornea.

It is one of the oldest infection diseases known to mankind. It is caused by chlamydia trachomatis micro-organism which spreads through contact with eye discharge from the infected person (on towels, handkerchiefs, fingers etc.) and through transmission by eye seeking flies. The primary infection affects and conjunctiva follicles and corneal involvement cause ulcers. Basically, trachoma is a socio economic rather than a medical disease. It is found in those areas where living conditions are bad and where people are poor, dirty, ill nourished ignorant. Trachoma goes through four stages: Ø 1-3 weeks the early sign is that the conjunctiva of the upper eyelid becomes red; Ø Small pink bumps appear on the conjunctiva of the upper eyelid, the upper part of the cornea becomes infected and inflamed; Ø Healing now starts with formation of scar tissue on the eyelids, the conjunctiva and the cornea; Ø The disease is, no longer, infections leaving scarring of the eyelids, the

51 conjunctiva and the cornea, together with the turning in of the eyelids and the scratching of the eye lashes against the cornea; leading to a loss of vision and possible blindness. Causes: Ø Caused by an organism chlamydia trachomatis. Ø Spreads by contact from one person to another through dirty hands, contaminated handkerchiefs or towels. Ø Flourishes among people whose surroundings are unhygienic and who are crowded together in an unhealthy environment where there is : lot of dust, poor sanitation, many flies, scarcity of water, open and dirty latrines, open drainage system.

Symptoms: ~ Redness ~ Itching ~ Tearing ~ Irritations. Treatment: Ø Clean the eyes if there is discharge. Ø Sulphacetamide eye drops 10% or 20% instilled at least four times a day for 6 weeks. Ø Advice on personal hygiene and daily washing of face. Ø Check other member of the family for trachoma. Glaucoma or increased intraocular pressure: Glaucoma is very dangerous and it occurs due to the increase in the intra ocular pressure. Glaucoma is not a disease but rather a complex of ocular disorders. The normal pressure level in the eye is 15 to 20 mm Hg. In glaucoma the pressure may be up to twice the normal. Normally the aqueous humour fills the anterior posterior chambers and permeates the vitreous humour. Aqueous humour is produced by the ciliary body.

52 The intraocular pressure is determined by the rate of aqueous humour production and the resistance to out flow aqueous humour from the eye. Normally a constant balance is maintained between the rate of formation and the rate of absorption of aqueous humour. The resulting increase in intra ocular pressure can damage the optic nerve. Glaucoma can occur at birth or develop later in childhood or adulthood. Types: (i) Chronic (open angle) glaucoma. (ii) Acute (narrow angle) glaucoma. (iii) Secondary glaucoma. (iv) Childhood glaucoma. Treatment of glaucoma can only prevent further loss of vision, it cannot bring back sight already lost. There are three types of treatment: Ø Medical-open angle Ø Surgical-open angle Ø Medical and surgical- angle closure Symptoms : (i) An occasional vague headache or itching about the eyes. (ii) An occasional blurring or cloudiness of vision. (iii) An occasional watering of eye. (iv) Diminished side vision. (v) Frequent and unsatisfactory changes of glasses. (vi) Occasional difficulty in the night vision. (vii) Haloes (rainbow ring around bulbs) appear towards evening. Cataract: Opacity of a lens or its capsule is called "cataract". The clouding may be through out the entire lens or may involve a small localized area. If it is confined to the periphery, the vision may be normal or only slightly reduced. If it is centrally located in the direct line of vision it can distort the sight at an early stage of formation.

53 The greatest loss that can be sustained by a contract is a restriction of the ability to perceive light. The vision is lost because the normal clarity of the lens is reduced and the lens cannot focus the rays of light into an image on the retina. Cataracts may be associated with injury, infection, metabolic disorder or toxic condition. Bilateral cataracts in children are often associated with nystagmus and retinal disease. Children with congenital cataracts can be improved by glasses (bi-focal), contact lenses and low vision aids. Cataract surgery involves removing to cloudy lens from the eye replacing it with glasses, a contact lens or a plastic lens. Without effective treatments cataract account for as much as 50% of the world's mass blindness and it is one of the world's leading causes of blindness. Common symptoms Ø Diminished vision Ø Double vision Ø Decrease insensitivity to colour Ø Poor vision in bright light and improved vision in dim light Ø Newly acquired ability to read without glasses. Causes: Ø Aging Ø Long duration of diabetes Ø Dehydration Ø Low levels of calcium Ø Cigarette smoking. Ø Congenital Ø Other eye diseases Ø Diabetes; certain drugs especially cortico-steroids. Ø Injuries to the eye In hot countries there are additional causes: Ø Solar and heat radiation in desert areas Ø Diarrhea in early life Ø Poor nutrition

54 Measures to prevent cataracts: Ø Increased awareness of the need eye for eye safety. Ø Taking of safety measures in certain dangerous jobs. Ø Ensuring the prompt surgical and medical treatment of eyes injures. Ø Early detection of other eye diseases which may lead to cataracts. Ø Monitoring of people taking those drugs which might form cataracts. Ø Control of diabetes. Cortical visual impairment: Cortical visual impairment is the total or partial loss of vision in a normal appearing eye caused by damage to the visual area in the brains occipital cortex. This type of damage is most often caused by loss of blood flow to the occipital cortex from either unilateral or bilateral. Posterior cerebral artery blockage. A patient with critical visual impairment often has little or no insight that they have lost vision, a phenomenon known as Anton's syndrome or Anton Babinski syndrome. Causes The most common causes of cortical visual impairment is oxygen starvation to the occipital lobe caused by blockage to one or both of the posterior cerebral arteries however, other conditions have also been known to cause cortical blindness, including: Bilateral lesions of the primary visual cortex. Side effect of some anti-epilepsy drug. Cortical visual impairment can be associated with visual hallucination, denial of visual loss, and the ability to perceive moving but not static objects. Macular Degeneration: This is a disease of the eye that results in central vision loss. It is more common among older individuals and is often hereditary. Macular degeneration is one of the more common causes of partial blindness in older individuals. The destruction or poor development is the macular (central) portion of the retina. Often undetected in young, its consequence is extremely poor central vision. Age related macular degeneration is one of the leading causes of visual impairment in the world and it presents as two forms.

55 Ø Dry or atrophic. Ø Wet or exudative. The atrophic form is more common than exudative, with about 90% of patients being diagnosed with atrophic age related macular degeneration. The exudative form of disease usually leads to more serious vision loss. It is more common in people over 65years of age and female. Causes: Hereditary factors, age, nutrition, smoking, hypertension are all risk factors. But the exact causes of age related macular degeneration are still unknown. The atrophic form the thinning of macular tissues, amorphous deposits and pigmentation in macula. Exudative macular degeneration occurs when new vessels from a choroidal neovascular membrane to improve the blood supply to oxygen to deprive retinal tissue. These new vessels leak blood and fluid causing damage to the surrounding tissues. Symptoms: Ø Gradual diminution of vision. Ø There may be shadowed area in the central visual field causing difficulty in reading. Treatment: Ø Zinc supplement and antioxidant vitamins may help to lower the progression of age related macular degeneration. Ø Laser photo coagulation is effective in sealing leaking in eyes with "wet" macular degeneration. Management: Patient with central vision loss may benefit from the use of low vision aids.

56 2.7 Educational implication of different eye Disorders: Albinism : i) Environmental concerns such as glare from the windows and light in a classroom must be addressed, since they may cause sensitivity and pain. ii) It is important to consider magnification aids and enhanced print for student such as longer font size and making text bold. iii) Teachers should consider minimizing in small clutter on maps and other diagrams. iv) The role of the orientation and mobility instructor is important in helping to familiarize the student with new areas particularly those which are subject to changing light. Amblyopia (lazy eye): Students with one damaged eye and one healthy one may require the good eye to be patched for a number of hour everyday to encourage development of the pathways from the weaker eye. Cataract: ●●●●● Problems in near and distant tasks. ●●●●● Poor colour vision. ●●●●● Unable to read and write ●●●●● High illumination needs for peripheral loss. ●●●●● Low illumination needs for central loss ●●●●● Difficult to read glare materials. ●●●●● Mobility is restricted ●●●●● Unable to perform in the daily living ●●●●● Also students will need time for adaptation activities to light change. Glaucoma: ●●●●● Adaptations to accommodate reduced Visual acuity or field of Vision, both factors would need to be considered, the student with reduced Visual acuity

57 may need to sit close to the front of the class to see board, low vision Aids as large print may be recommended. ●●●●● Able to read print to a limited extent. ●●●●● Extreme difficulty in travel. ●●●●● Unable or difficulty in reading at night ●●●●● Difficulty in seeing at night. ●●●●● Difficulties in scanning & tracking. ●●●●● Avoid vigorous activities. ●●●●● Reduced Peripheral Vision would have an impact on student's mobility in the classroom. ●●●●● Frequent hospital appointments may interfere with Schooling. ●●●●● Cataracts can affect student's visual acuity and cause decreased reading efficiency and problems seeing the board due to a cloudy Lens. Hypermetropia: ●●●●● Difficulty in reading and other near Vision activities. ●●●●● Eye strain / Fatigue due to excessive accommodation. ●●●●● Learning impacted by reduced or difficult concentration. ●●●●● Interaction with others may be affected by lack of ability to recognize facial expressions and body language. ●●●●● Low Vision aids and text enlargement may assist with the reading of curricular and instructional materials. Myopia (Nearsightedness): ●●●●● The use of eye glasses, contact lenses or low vision aids has proven particularly helpful in viewing distant objects. ●●●●● Learning may be infected by reduced or difficulty with concentration. ●●●●● Students may experience visual fatigue when asked to do a lot of reading. ●●●●● Inability to see black board, objects at a distance.

58 ●●●●● Lack of interest in outdoor games and recreational activities. Nystagmus: ●●●●● Students with nystagmus will often require environment support with lighting. ●●●●● Colour contrast test and other magnification tool will often be required helpful. ●●●●● Tasks such as copying from the board will be difficult as it involves frequent changes of focus, providing student with own copy of work to be copied would be preferable. ●●●●● A student with Nystagmus often suffers from vision fatigue especially when expected to do a lot of reading. ●●●●● Stress also affects the student and has been seen to increase the involuntary movement of the eyes. Optic Atrophy: ●●●●● Problems in reading, if reading into the blind field area. ●●●●● Problems in mobility ●●●●● Good task lighting and high contrast materials (black & White) may improve readings speed. Retinal Detachment: ●●●●● Where students have field loss it is important to recognize what part of their vision is missing and avoid placing objects in these are. ●●●●● Inability to concentrate ●●●●● Bumping into objects, ●●●●● Students with tendency to develop retinal detachment should avoid blows to the head in physical activity; if this occurs then parents should be notified immediately. Retinitis Pigmentosa (RP): ●●●●● The student will benefit from preferential seating and may exhibit eccentric viewing or frequent head turning to compensate for the reduced visual field.

59 ●●●●● Due to reduced vision in low light the student will benefit from good, even lighting. ●●●●● Mobility may also be affected due to reduced visual field. Retinopathy of Prematurity: ●●●●● Depending on the severity of the visual impairment which may vary from low vision to blindness the student will require either large print or Braille, If the student is not a Braille user, he will likely need low vision aids used as magnifiers or a monocular. ●●●●● It is important to be aware of proper illumination for the student while trying to avoid glare. ●●●●● Orientation and mobility training is essential. 2.8 "Check your progress" 1. Low Vision 3.7.2 The needs of people with low vision 3.7.3 Teaching Implication 3.8 Check your Progress 3.9 Let us sum up 3.10 References 3.1 Introduction As much as 90% of what we know is learned through vision. Children with no, partial or distorted vision will have difficulty in accessing information, leading to a typical knowledge and skill development. Unless aggressive efforts are made to Compensate for the reduced access to the environment, Children with visual impairment may have limited development of concepts and the world around them. There is no separate psychology of persons with visual impairment. There are some psychological effects which emerge because of disability. A teacher should necessarily study the psychosocial implication of blindness in order to guide the children properly. The process of growth and development for any individual child is at same time similar to and different from that for any other child. It is similar because growth is sequential, with identifiable stages through which all children progress; it is different because each child progress at his own unique rate as a result of his own individual needs. This principle applies visually impaired children as well, and in general their similarities are greater than their difference from sighted children. The rate of growth of visual impaired children is affected by the visual impairment. However, visual impairment has either direct or indirect influence on the rate of growth and development of visual impaired children. Development is normally defined as a continuous process of change. Studies on child development primarily focus on language development, motor development, personality development, emotions, cognitive functions, and the inter-relationship between them. Development in these areas is considered essential for every child

65 irrespective of his/her disability. However, blindness results in some implications on the psycho-social developments of these children. This chapter enumerates the developmental stages in the life of the child, psycho-social aspects of visual disability, mannerisms and verbalisms, and the implications of blindness on education. The Success of students with visual impairment is measured by their ability to adapt to the regular curriculum and classroom expectations, and to perform the same way as their peer Although academic success is important, it should not be the only yard stick in measuring a student's future success at employment, life after school and personal independence. Special educators for children with visual impairment recognize that a unique, specialized or disability specific curriculum is essential for all children with visual impairment to ensure optimal access to the academic curriculum in the schools, as well as future success in life. Development is normally defined as a continuous process of change. Studies on child development primarily focus on language development motor development, Personality development, emotions Cognitive functions and the inter relationship between them. Development in these areas is considered essential for every child irrespective of his disability. But Blindness results in some implication on the psycho- social development of these children. Blindness is a medical phenomenon. It relates to impaired sense of vision. Stated simply, it only means that the person suffers from the loss of sight. But the matter is not so simple. Blindness in all countries through ages, has come to develop as a connotative word; it evokes different emotional reactions in different persons. The societies, across the globe have developed their own perspective of blind persons, regarding their capabilities and their limitations. Parents, as part of the community, share social ways and attitudes but when a blind child is born to them, they find their personal ways to cope.

96%

MATCHING BLOCK 45/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

The visually impaired person and his/her family face serious social challenges. Directly and indirectly visual impairment interferes with many daily activities. In the case of adults the possibilities for gainful employment are severely limited as is their participation in many activities. To this is often added a loss of social status and self- esteem. The physical limitation and psychological implications of visual impairment 66 cannot be measured in exact monetary terms. Nevertheless, it is clear that they diminish the quality of life not only for blind persons but for their families as well.

As a person with visual impairment adjustment to life in a seeing world is a complex process. After carrying out a review of studies on psychological adjustment of low vision children, Morse (1987) concluded that children with low vision tend to be more unsettled by the limits of their vision than compared to those whose handicap are more severe. The dynamics which impels one to adjust is necessity. But blind persons vary in their response to this demand of necessity due to various factors, among which are - i) age of onset of blindness, ii) Degree of vision and type of vision and type of vision loss iii) Prognosis and iv) Socio economic status of the family. The visual system's immediate and simultaneous processing of extended spatial information affords fundamental information of depth, object permanence and constancies, brightness, and color. Loss of vision requires the successful integration of successive stimulus information from intact sensory systems, primarily touch and hearing. Such loss impacts negatively on perceptual, motor, cognitive, as well as social interpersonal behavioral development. The amount of visual difficulty depends on the eye condition, so some babies and children have more difficulty than others. Most babies with limited vision tend to see very little in the early months, though the vision of most will improve. The rate and degree of improvement of vision varies in each child. In a very few eye conditions it is known from early on that the child will not develop any more vision. For most children with limited vision, there is uncertainty and it is important with these children to help them develop their vision to its maximum potential. The possible effect of visual impairment on attachment and socialization has also been suggested, and the increased prevalence of specific emotional and behavioral problems, as well as developmental delays, among visually impaired children has been established Therefore the mutual effect of emotional problems on the development of visually impaired children, and vice versa, is of great importance. Such an understanding may influence treatment strategies that are related to development at different ages, particularly among infants and young children like these are.

67 3.2 Objectives : After studying this unit the teacher trainees will be able to - ●●●● Describe the psychosocial implication of blindness. ●●●● Discuss the implication of child blindness for the parents and the family. ●●●● Analyze the effects of family and community attitudes on the blind child. ●●●● Explain his or her own role as a teacher in relation to the visually impaired child, parents and the community. ●●●● Describe the

SEVI-31 with glossary for alignment.docx (D127037367)

the educational needs of children with low-vision. 3.3 Psycho Social Implications of Visual impairment : 3.3.1 Basic Effects of

Blindness : The effects of Blindness are basically cognitive, since blindness relates to the sensory deficit of vision and because senses are the gateway to knowledge. Moreover vision is the most actively used sense of man and hence his knowledge grows chiefly from his visual experiences. The resulting effects have been discussed widely but the most accepted interpretation has come from Dr. Berthold Lowenfeld. In his own words, "Blindness imposes three basic limitations on the individual". 1. In the range and variety of experiences 2. In the ability to get about 3. In the control of the environment and the self in relation to it. These three obstacles to independence and self-fulfillment are responsible for the special educational provisions for the blind child. A brief look at the three limitations may be helpful in understanding the losses in depth.

68 It has been estimated that 90 – 95% of all experiences comes through the eyes. Vision is the major mode of acquiring information about people, places and processes. Therefore, the blind child, by definition, is experientially deprived. The blind child learns in pieces. He learns in a fragmentary way. He requires enough time to put, these bits and pieces together to a clarity Concept which is not exactly like ours but which is enough like ours so that we can communicate. And that is the restriction in the 'range and variety of experiences'. Secondly blindness tends to create a very sedentary kind of existence. A blind person will just sit unless he is pulled out, motivated to get out and move about independently. He sits because of fear. He sits because of lack of skill in using information available in his environment and lack of skill in moving about within it. Certainly the ability to get about is restricted. Thirdly a blind person talks loudly in a room that is too small for a loud voice or he talks to a corner, or to an empty chair rather than to another person, the common reaction is akin to a silly man. But it is not silly. It simply shows how a blind person is very much at his disadvantage. Not knowing where one is, being unable to control one's environment and oneself in relation to it is a significant deficit.

Verbalism : Verbal learning without adequate concrete experience is considered to be a significant problem in the education of the blind. The visually impaired child frequently accepts verbal descriptions from the sighted instead of having them based on his own concrete experience. This is not surprising since he has limitation in exploring the world around him and at the same time, he is tagged constantly in visual term. In gaining concrete experience he cannot touch objects that the sighted can see, such as the moon, waterfall, a rainbow, certain animals, fire or lightning and he cannot conceive of colours therefore, he must accept many visually oriented verbal descriptions from the sighted. The sense of sight permits much greater perceptual activity than the sense of touch. Although in time he is able to describe visual concepts well verbally he still may have a hazy, partial and inaccurate understanding of them. This phenomenon is called verbalism which is closely related to concept formation. Mannerism: The psychological implication is that blindness does not mean 'loss of life' since

69 blind persons are more like than unlike sighted persons in terms of basic needs. The educational implication is that the reduction of experience caused by blindness can be overcome by appropriate training to the affected individual. Education and rehabilitation programmes for visually disabled children are growing in large numbers in the present scenario and the independence of disabled person is assured in every respect. These objective effects certainly result in some mannerism such as head movement, tapping on the floor, clapping to find the way out etc. Conscious efforts must be made by the teachers to teach the visually disabled child, what mannerism is acceptable and which ones are unacceptable for his/her inclusion in the society. Community Attitudes and Reactions : Unfortunately the deficits are caused by the community as they occur to the individual. The reactions, however, vary from community to community depending on its traditions, culture and belief. Certain communities used to kill a disabled child as the community which depends on skills of war for its survival could not accord a place to a handicapped child. As the society progressed towards becoming a welfare state rather than warfare state, so did the changes occur in the total outlook. The blind person became members of the society who needed to be looked after but not at the equal level with others they were to live on 'charity'. It has also an under tone of religious belief. Today, the scenario is changing. The Community is based on the principles of equality and fraternity. Later is a rare phenomenon. The motto is equal opportunities for all including handicapped people. But this motto is a recent development. It is dangerous to generalise without sufficient experience and exposure to the characteristics of blind. As one comes across very few blind person in life-time, we tend to generalise about blindness on the basis of limited experiences. Due to the place accrued to the blind being that of 'charity' general tendency is to perceive a blind person as one who can make a livelihood only through begging, hence, blindness implies low level of living. They depend on senses of hearing and touch as the light is denied. People need to be educated to write about blindness accurately and carefully. The public needs information not only on the realities of blindness but also on the techniques which make both the blind and the sighted person comfortable. How do you manage a blind person? How do you behave when you teach a blind person? How do you show a blind person where to sit down? How do you talk to some of one who is blind?

70 Need For Community Orientation : People need to be educated about visual disability. There is a need to present the positive sides of the lives of disabled persons too, to change the stereotype attitude of the society. The community needs information not only on the realities of visual impairment but also on the techniques which make both the visually impaired and sighted person comfortable. Print and non-print material on themes such as how do you manage a visually impaired person? etc. need to be developed for orientation of the community. Some people are so inhibited that they hesitate about being with a visually impaired person. They also become hyper sensitive. They are afraid to use certain words such as 'see' and 'look'. Regular classroom teachers are frequently faced with this problem and instead of saying "look at this to mean explore and learn to understand this". Most people are well intended but miss-directed in this way. They do not want to offend a visually impaired person. Proper community education is the answer to these misplaced misconceptions. Parental Reaction to Blindness : We form our reactions to unknown and inexperienced on the basis of our general impressions. Blindness causes many types of reactions. When we come across a blind child, the general attitude is of sympathy or at times neutrality but seldom of empathy. The reason is the general reaction "Such things happen to others and not us". But when it does happen, the parents feel at a loss. For so many social-Personal and psychological reasons, the reactions occur on a continuum of neglect to over protection. Due to inability of most parents to understand the implications of an impairment, the impairment is perceived as a handicap. On one extreme is the response of neglect, because it is felt that a blind person is devoid of all normal human functions of being an active Member of the society. Not only this, even parents at times feel the birth of a blind child to be the result of some sin. Hence in their own frustration, the child is ignored and naturally, 'the expectancy prophency' come to be true, the child develops into a person who cannot contribute socially or economically to the society. Neglect causes certain personality problems but the child has to learn certain basic living skills. Over protection is more dangerous. It denies the child of all the natural demands or expectations of the society.

71 The social structure is such that we try to say or act what is socially acceptable. Real feelings are rarely expressed especially when they are contrary to the socially desirable ones. The parents of a blind child at times, pose the full acceptance of the blind child as an overt behavior because today society expects parents to stand by their children. But it is difficult to accept a child who becomes a liability, a reason for social talk and criticism. Overt rejections is manageable but covert rejection does not deceive a child. It hurts him psychologically. It affects not only his growth and social relationships but also his own self-concept, the very basic of a person's development. Role of peer groups : Peer group influence is substantial in the making of individuals whether it is in the childhood, adulthood or in old age. A disabled individual should have better interaction with other disabled persons of the same age group. Experiences have revealed that disabled children integrated with the mainstream programme tend to accept the disability condition and move forward for constructive life. Therefore, disabled persons should be main streamed as early as possibly to experience the positive effects of personality development on the individual with disability. Role of Teachers : The teachers should help the parents to observe disabled children in the classroom setting and notice the nature of training he or she requires –proper language, Cognitive, motor, emotional and social developments. The teachers should encourage parents to ask questions and clarify doubts. Moreover, the parents should be oriented by the teachers to identify the areas where the child needs maximum assistance. In general. The close collaboration with the teachers and parents of disabled children could cast a tremendous impact on the overall development of the child. Often, teachers are looked upon by parents and disabled children as the major source for guidance. As teachers are trained to handle children with disabilities in the professional way, their influence on the personality development of the child is undisputable. They should act as mentors for children with disabilities and their parents. If possible, making visits to the families of children with disabilities and interacting with the child, their parents and siblings may have a positive influence on the personality development of the child.

72 Psycho-Social Effects on the child : Really speaking, psycho-social development of a blind child is not affected so much by blindness as it is disrupted by the emotional overtones of blindness, for the parents and the community. It is now a well-known fact from research that children tend to achieve as much and only as much as their parents aspire them to achieve or the significant persons in their environment expect them to achieve. But, once, the community does not treat them as individuals they are lost in a crowd, the crowd of blind persons-beggars, musicians or do whatever they like. Once, the parents stop treating the child as a developing individual, once they refuse to accept his capabilities and limitations both, in a realistic and positive manner, his self-concept is bound to be severely affected. Overprotection robs him of his independence, neglect turns him to undesirable behaviour. 3.4 Factor

100%

MATCHING BLOCK 48/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

affecting implications of Visual impairment: Age of onset, degree of vision, type of vision loss, prognosis, and socio economic status of the family. 3.4.1.

Age of Onset : Development "norms" are based on observation of sighted children. Although it - appears to be true that the more likely he/she is to develop at a normal rate there is little research to support a direct comparison of blind children to sighted norms. In fact current research suggests that blind children may have their own set of norms (i.e. they may not follow all of the same sequences, in the same order, at the same time, as sighted children). Human life can be divided into four broad stages; Infancy, childhood, adolescence and adulthood - the first three of which correspond roughly to the Piagetian stages of sensory-motor (0-2), Pre-operational(2-7), Concrete operation(7-12) and formal operation (12 onward). The stages can again be divided into early and late sub-stages. In shaping personality and attitude each stage has its own contribution to make. Orientation is the ability of the visually impaired child to perceive and understand his/her position and location within a given environment. Mobility is the ability to move within a given environment. This ability does not suddenly appear at a specified time or age, but has an underlying conceptual foundation which begins at birth. For visually impaired infants, many factors contribute to the qualities of these emerging

73 conceptual foundations. Initial mobility factors are largely motor based, and depend to a great extent on the development of the motor system. Milestone skills such as head control, sitting unsupported, independent hand/arm use (as in grasping and reaching) creeping / crawling, standing alone and walking independently are all pre- mobility skills. In childhood - the period between 6 and 12 the chaotic and disorganized emotional life of the infants becomes more stable, and definite social relations are established. The main characteristic of this period is socialization of the child owing to more diversified, and at the same time, more selective activities. A child who loses his sight during this period is suddenly pushed off the track which he was following so long. Emotional disturbance may not be as severe as we understand in the adult sense, but social bonds being snapped, his ability to establish social relation may become less effective. Isolation from the peer group and lack of activities tend to produce anxiety and tension which, when unresolved may lead the child to non-coping and non-adjecutive, mannerist behaviour and verbalism. The effect of onset of blindness in adolescence period is more complex. Theoretically it may be true that, as the individual has already passed through the previous stages undisturbed there would not be great developmental deficits in the psychomotor and cognitive areas due to blindness, but from the personality point of view, the effect may be highly damaging. The human being who is getting ready both physically and mentally to become a full-fledged individual in this world, suddenly becomes a non-person at the blow of blindness - at least, he or she feels so. The budding self-image and self-concept of the adolescent, who already having the normal quota of "Storm and Stress" of this period is shattered with the onset of blindness. An adult also experiences almost the same emotional instability after losing eyesight. 3.4.2. Degree of

83%

MATCHING BLOCK 49/112

SEVI-31 with glossary for alignment.docx (D127037367)

vision: Visual impairment refers to a significant loss of vision in both eyes which may vary significantly, which means that each student with low vision or blindness needs individual adjustments to learn most effectively. There are two main categories of visual impairment: Low vision

and blind. The classification of

76%

MATCHING BLOCK 50/112

SA

Rajesh E- TEXTBOOK ON BASICS OF VISUAL IMPAIRM ... (D143341256)

visual impairment varies worldwide. The "WHO" classifies levels of visual impairment based on visual acuity and visual field limitation, and 74 defines blindness as profound impairment. The "WHO" definition of blindness specifies visual acuity less than 20/400 and or remaining visual field less than 10 degrees in the better Seeing Eye. Visual acuity of 20/70 to 20/400 (inclusive) is considered moderate visual impairment

of or low vision. The national eye institute defines low vision more loosely as a visual impairment not correctable by standard glasses, contact lenses, medication or surgery that interferes with the ability to perform activities of daily living. Though the dictionary meaning of blindness is lack of sight that is total absence of vision, in reality we find blind persons not all of them are totally blind but with varying degree of visual loss. We would get different degree of visual ability in the intermediate stages like "light perception" (the ability to differentiate between light and darkness) "light projection" (the ability to detect the direction and source of light), and gradual increase in low vision up to 20/200 ft.. Different degrees of visual disabilities affect the individual adjustment to their handicapped differently. Every case requires individual attention. 3.4.3. Type of Vision Loss: There are some children who are not blind in the medical or legal sense of the term but their visual impairment is serious enough to call for special help in education. They are called partially sighted. They are not admitted in to the institutions for the visually handicapped as they do not generally use touch as the main mode of learning. With the help of optical and mechanical aids, they can read prints. But due to constant pre- occupation with vision and efforts to see a little better, the partially sighted child, who acquires somewhat abnormal gaits and posture, may become self- centered and sluggish in social behavior. Most of eye disorders is considered to affect the human being which is most commonly of two types. One is adult vision problems which consist mostly. i) blurred vision (Called refractive errors) ii) Age related macular degeneration iii) Glaucoma iv) Cataract v) Diabetic retinopathy. On the other hand, most of childhood vision problems are like (i) Blurred Vision (called refractive errors) (ii) Crossed eyes (called strabismus) (iii) Lazy eye (called amblyopic) (iv) Albinism.

75 Blurred Vision (Refractive errors) : ●●●● Near sightedness (called myopia) is when we can see clearly the close ups but blurry in the distance. ●●●● Farsightedness (called hyperopia) is when we can see clearly in the distance but blurry ups close. ●●●● If you are older than 40 and have trouble reading small print or focusing a close-up this is usually due to a condition called Presbyopia. ●●●● Astigmatism is another condition that causes blurred vision but it is because of the shape of the cornea. Crossed eyes (Strabismus) : Strabismus occurs when the eyes do not line up or they are crossed. One eye however, usually remains straight any given time. Common forms of strabismus include - ●●●● Esotropia: One or both eyes turn inward toward the nose. ●●●● Exotropia: One or both eyes turn out, also called wall -eyed. ●●●● Hypertropia: One or both eyes turn up. ●●●● Hypotropia: One or both eyes turn down. Lazy Eye (amblyopia): Amblyopia often called lazy eye is a problem that is common in children. Amblyopia is a result of the brain and the eyes not working together. The brain ignores visual information from one eye, which causes problems with vision development. Treatment for amblyopia works well if the condition is found early. If untreated, amblyopia causes permanent vision loss. Albinism: Albinism is a pigment deficiency causing several physical condition including vision problems. People with albinism often have low vision including severe light and glare sensitivity.

76 Effects on Vision : Albinism is a non-progressive condition and so as the individual ages it will not. Albinism can cause Photophobia (an aversion to bright light) A student may notice their vision is worse in bright light and better in dim light (especially central vision). Along with light sensitivity the student may also have astigmatism, lowered visual acuity and nystagmus (side to side rhythmic eye movement). Cataracts: Cataracts are the leading cause of preventable blindness worldwide. They are responsible for over 50% of the world's blindness, over 20 million people. Cataracts are a clouding of the lenses of the eye that cause light to be diffused as it enters the eye impacting the clarity of the visual image. Most cataracts are a natural result of aging out they can also happen due to trauma to the eye. Effects on Vision : The lens of the eye is affected by cataracts. Often the lens becomes cloudy and prevents light from refracting onto the retina at the back of the eye. Retinopathy of Prematurity Retinopathy of prematurity is characterized by the abnormal growth of blood vessels in the retina of some premature infants. The use of oxygen administered to premature babies in incubators was suspected as a possible cause of the abnormal growth of the blood vessels. Other factors include low birth weight, premature birth 32 weeks or younger and the baby being severely ill at birth. Effects on Vision: The retina is affected because blood vessels do not reach the edges so blood flow is disrupted. If there is normal growth of the blood vessels, the area is well supplied with nutrients and oxygen. The optic nerve and macula are affected as well as the mid and far periphery. Retinopathy of prematurity can range from a mild reduction in visual acuity to complete retinal detachment and blindness. Glaucoma: Glaucoma is the most common eye disease, affecting more than 80 million people worldwide. Glaucoma involves damage of the optic nerve, usually caused by 77 fluid buildup and increased pressure inside the eye. The result is a loss of peripheral vision and often difficulty seeing in dim lighting. Effects on Vision: Early detection and intervention can control the pressure and reduce the impact on vision. Blindness can occur in a few cases, the combination of eye structures affected with the addition of amblyopia caused by visual deprivation in the formative years contribute to the visual impairment. Peripheral vision often first affected as nerve fibres from the peripheral retina are most susceptible to raised pressure. Some students experience photophobia.

100%

MATCHING BLOCK 51/112

SA

TFG AMARA NAHEED (0-JL).docx (D124054780)

Age related Macular Degeneration (AMD) : Age related Macular Degeneration (AMD) is the

foremost cause of Vision loss among all over the world people who are 60 and older. AMD involves damage to the macula in the back of the eye, resulting in loss of central vision to effect on many tasks, including reading and writing. This can result in a loss of independence. Retinitis Pigmentosa(RP) : Retinitis Pigmentosa is the general name given to a wide range of genetic eye conditions predominantly characterized by problems with the rod photoreceptors, however in advanced cases the cones may also be compromised. Specific eye conditions associated with Retinitis Pigmentosa are Rod Cone Dystrophy, Leber's Amaurosis and Usher's Syndrome. RP usually progresses slowly. Cataracts and retinal swelling are also associated with retinitis pigmentosa. Effects on Vision: Usually the rods are more affected than the cones meaning night vision and movement of things are compromised. There will also be a loss of peripheral vision. If the cones are affected then there will be central and colour vision loss. Stargardt Disease : Stargardt disease is the most common form of inherited juvenile macular degeneration, occurring in one in every 8000 to 10,000 people worldwide; It causes gradual loss of central vision. It usually develops during childhood or adolescence resulting in a loss of the center part of the visual field.

78 3.4.4 Prognosis What is Prognosis? : "Prognosis means what is expected in the future?"

100% MATCHING BLOCK 52/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

In general vision loss does not improve over time. There are exceptions of course such as when you are correcting a problem such as amblyopia or

near sightedness.

100% MATCHING BLOCK 53/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

In addition, as a visually impaired infant grows and develops, they may be better able to use their vision and demonstrate what they see, so that it appears as though improvement has been made. But vision loss that is present from birth or early childhood, particularly when it occurs with other disabilities will usually not get better. However with the right training, technology and other assistance,

a

81% MATCHING BLOCK 54/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

child can live a full life even with vision loss. Children with vision impairment may have some delay in development related specifically to not being able to interact with their environment visually since much of what a child learns comes from visual clues. As

a

100% MATCHING BLOCK 55/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

child receives vision supports and early intervention services, these gaps will close. If

a

80% MATCHING BLOCK 56/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

child has other disabilities, along with vision loss, one can still give one's baby a high quality of life through early intervention services, adaptive devices and other methods of treatment. 3.4.5 Socio economic status of the family : The

family plays in shaping our personality. It is the first social environment that a child gets in its life. It has been proved that the adjustment problems of each individual member in the family are usually related to inter dependencies with other members. The culture, socio-economic status, the educational level of the family particularly the parents and their relation with the visually handicapped child determines the level and quality of adjustment of the child to his own disability and to the society. The role of the parents, especially the mother, is most crucial in this process. An analysis of the global distribution of visual impairment shows a disproportionately large prevalence in low income developing countries. In these countries cataract and trachoma are the greatest causes of avoidable blindness. The lack of and inequity of access to prevention and eye care services severely limit in these regions

95%

MATCHING BLOCK 57/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

of the world. The lack of economic development is a factor that aggravates the prevalence of visual impairment. For this reason, blindness prevention programmes must concern themselves not only with the elimination of avoidable blindness but also with concurrent economic development. The cost of rehabilitation and care provided to the visually impaired are the most obvious. Less apparent but just as significant however

is the indirect cost resulting from the loss of productivity. Family can be the most important factor in a child's success in recalling his or her full potential. The efforts of a child family to provide life experiences and obtain necessary services can make a tremendous difference. In addition to finding knowledgeable, medical and educational professionals who can help meet the needs of their children. Families can help a visually impaired or disabled child grow and develop by having expectations that their child will in fact do exactly that. When children are a part of family life, they learn about the world around them about the people in that world and about themselves as a person as well. For that reason, It is important for a child to be involved in meal times in home, even if she may not eat solid food using a fork, knife, or spoon, sitting at the table with the rest of the family gives her the chance to be social and to communicate. Perhaps you may need feed her before everyone else because she's on a particular schedule or is to be fed, but finding ways to bring her to the table when the rest of the family eats can be important for her and for all as

97%

MATCHING BLOCK 58/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

family. 3.5 Effect of visual impairment on growth and development: Physical, Motor, Language, Socio-emotional, and cognitive development. 3.5.1.

Physical Development The child's rate of physical growth begins to taper off after toddlerhood, the period when physical development is at its greatest. Yet body proportions continue to change, and motor skills continue to be refined at a relatively fast rate, enabling children become more adept at dealing with their own needs and coping with their physical surroundings. By the age of 5, the average child stands 43 inches tall (about 3.5 feet), which is just over double the birth length, and weight 42.8 lbs., approximately five times the weight at birth. At birth, the head measures between 12 to 14 inches in circumference. By the first year it has increased 33 percent, and at the fourth year the head has increased approximately 48 percent. And by the end of the sixth year,

80 the head has attained almost 90 percent of its adult size. The brain, growing in relation to cranial growth, has attained 75 percent of its adult weight by the fifth year, as the billions of nerve fibers become increasingly myelinated and the dendrites in all layers of the cortex increase in both size and number. These maturation processes will enhance the connectivity and transmission of nerve impulses, which is critical to more complicated brain functions. Physical Changes during Preschool Years By the time children enroll in nursery school or kindergarten, there have been noticeable physical changes in their bodies. This is largely due to a growth spurt that affects height, as well as to the preschooler's participation in numerous and diverse physical activities, which affect muscular growth and body building. Changes in postural patterns also become quite evident during the early years. Force of gravity. The force of gravity affects the body (the center being the trunk), whether sitting, standing, or running. Each child must maintain equilibrium in order to produce good posture and balance. With age, body proportions change, and the centre of gravity drops lower in the trunk. This makes it easier for the child to maintain equilibrium in the standing position Type of body build. Posture is also affected by the child's body build. Correct posture is also influenced by the strength of the bones, the firmness of the muscles, and the kinesthetic sense. Course of development. The stages of the child's development are another factor to consider the early phases of locomotion, for example, influence certain parts of the body, such as the neck muscles or the lumbar curve in the lower part of the back. When walking, the weight of the body falls on the inner part of the foot, resulting in the foot's sagging in the area of the ankle. Interactions with the environment. Environmental factors, such as nutrition, rest, and activity also are important to posture. The child now has incentives to excel in certain areas, such as sports, to be physically attractive, or to perfect certain motor skills. All of these may encourage a child to learn proper body balance and posture.

81 3.5.2. Motor Development Generally, either no delay or only slight delays have been reported in motor- skills of blind children that require stable, in-place movement (such as sitting, rolling, and standing alone). However, more severe delays have been reported for those associated with locomotion (holding-up head, crawling, creeping and walking). There can be a longer delay between crawling and walking for children who are blind relative to their peers with vision. Motor skill development rapidly accelerates in the physical play world through such activities as jumping, climbing, running, and tricycle riding. Knowing what preschoolers are physically capable of undertaking and their degree of efficiency is important not only to parents but also to day-care and nursery-school teachers, people who will be structuring their physical activities. Adults need to develop children's motor skill activities so that they may alleviate any frustration. Hand

97%

MATCHING BLOCK 59/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

Although the hands are a major perceptual organ, a blind infant has significant developmental delays in his ability to employ his hands functionally. Even at 5 months a blind infant's hands will be fisted and held at shoulder height. There will be no mutual fingering, no engaging at the midline. At this age, a sighted child practise coordinated reaching and transference of objects from one hand to another. This delay in hand utilization will result in delayed fine motor and gross motor development.

100%

MATCHING BLOCK 60/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

Body A blind infant usually achieves control of his posture at approximately the same age as sighted Infants through the following normal progression: ●●●● sits alone momentarily ●●●● rolls from back to stomach ●●●● sits alone steadily ●●●● takes stepping movements when hands are held ●●●● stands alone ●●●● bridges on hands and knees 82 However, the achievements that require self- initiated mobility are significantly delayed: ●●●● elevated on arms in prone ●●●● raising to a sitting position ●●●● pulling to a stand ●●●● walking alone Until a blind child will reach out to grasp a sound cue (12 months), he will not move out in space either on hands and knees or feet.

Milestone's in Preschool Motor Developments. Age Gross Motor Skills Fine Motor Skills 2.5-3.5 Walks well; runs in straight line; Copies a circle; scribbles; can use years jumps in air with both feet eating utensils; stacks a few small blocks 3.5-4.5 Walking stride 80 percent of adult; Buttons with large buttons; copies vears runs at one-third adult speed; simple shapes; makes simple and catches large ball, but stiff- representational drawings 4.5-5.5 Balances on one foot; runs far Uses scissors; draws people; copies years without falling; can swim in water simple letters and numbers; builds for short distance complex structures with blocks 3.5.3. Language Development The foundation of communication starts in the earliest days, when babies express their feelings and parents respond to their cries or vocal sounds. This helps babies learn to influence their parents and to attract their attention. During the first year they become more purposeful in communicating their wishes and needs. This is done through vocal and emotional expressions, eye contact and/or body movements. In the second year, children start using language to communicate their wishes and needs, to request and refer to things and to draw attention to events of interest. The toddler years are typically the time of great language development as children begin to make connections and verbally label and identify objects. Children who are 83 blind or visually impaired will not have the same opportunity to casually observe and make connections with gestures and materials in their environment. Unless the student was intentionally taught through direct experiences paired with language, their language development will undoubtedly be delayed. To encourage the student to develop language, it is important for the student to be exposed to good language models in active learning environment. The following strategies can help a student develop their language skills: ●●●● Pronounce the language properly. ●●●● Speak with grammatical accuracy. ●●●● Build vocabulary. ●●●● Understand and produce longer stretches of speech, such as stories, directions, or instructions. ●●●● Use the language to accomplish purposes and get things done. ●●●● Use words and ways of speaking appropriate for different situations. ●●●● Interact with other people appropriately when talking with them. ●●●● Understand more about what the people are like and why they behave the way they do.

Verbalism It is common for a student to talk about people, objects, and events without having the understanding of the concepts. Because they haven't had the experiences related to the topic, but have heard others talk about the said topic. Having a vocabulary or language without the understanding is called verbalism. It is the ability to talk about a subject without the concepts or understanding related to it. Echolalia Many students who are blind or visually impaired learn to talk by echoing or copying phrases or sentences even if they do not understand it. They may echo what they just heard, or have delayed echolalia where they repeat language heard earlier in association with a particular subject. Sustaining Conversations Students who are blind or visually impaired also can have difficulty sustaining conversations. They can tend to focus on their own interests and not appear to have 84 an interest in others. Students may need explicit instruction in participating in conversations. Preschooler's language development can be improved responding to an encouraging young child's speech, Adults can do a great deal to help facilitate overall language development. Adults should consider the following suggestions: (1) Establish a satisfactory speech model. (2) Encourage verbal and nonverbal communication. (3) Provide experiences that will make words meaningful (4) Encourage listening and attention skills. (5) Encourage speech as a substitute for action (6) Use exact terminology and talk with children at their level. 3.5.4. Socio-emotional development During early childhood, children start to develop a "self-concept", the attributes, abilities, attitudes and values that they believe define them. By age 3,(between 18 and 30 months), children have developed their categorical self, which is concrete way of viewing themselves in "this or that" labels. For example young children labels themselves in terms of age "child or adult", "gender", physical characteristics "short or tall" and value, "good or bad." The labels are used to explain children's self-concept in very concrete, observable terms. Children's social-emotional development influences all other areas of development: Cognitive, motor, and language development are all greatly affected by how a child feels about herself and how she is able to express ideas and emotions. Professionals sometimes define healthy social-emotional development in young children as early childhood mental health. Healthy social-emotional development includes the ability to: 1. Form and sustain positive relationships 2. Experience, manage, and express emotions 3. Explore and engage with the environment Children with well-developed social-emotional skills are also more able to : Express their ideas and feelings ●●●● Display empathy towards others ●●●● Manage their feelings of frustration and disappointment more easily

85 ●●●●● Feel self-confident ●●●●● More easily make and develop friendships ●●●●● Succeed in school Social-emotional development provides the foundation for how we feel about ourselves and how we experience others. This foundation begins the day we are born and continues to develop throughout our lifespan. The greatest influence on a child's social-emotional development is the quality of the relationships that he develops with his primary caregivers. Positive and nurturing early experiences and relationships have a significant impact on a child's social-emotional development. They also influence how the young child's brain develops. Social interaction Several researchers have noted that whereas sighted children spend most of their playtime interacting with other children, children who are blind spend about half their time in solitary play. Children who are blind are also more likely to choose to spend playtime with adults than age-peers. Blind children in nursery school were observed to have severe difficulty in social interactions with sighted peers. In contrast to normal exploration, behaviours such as eye-pressing, body-rocking, and head-nodding can present serious problems. Such behaviours, which are described as "stereotyped behaviours", "blindisms," or "mannerisms," are prevalent among children who are blind or visually-impaired, although they are not found only in this population. The behaviours usually decrease with age, but can persist to adulthood. Possible reasons for these behaviors include monotony, boredom, stress, and excitement. 3.5.5. Cognitive Development A general issue relevant for school aged children is the possible impact of vision impairment on areas of cognitive development that are associated with interpreting information available to the senses. Examples of such areas are classification, conservation, spatial knowledge, and memory. Cognitive development refers to such skills as reasoning, storing and remembering information, seeing relationships and differences, classifying things, defining and describing, evaluating, comparing and contrasting, inventing, problem solving and other higher order skills. Non-disabled children of this age group are usually able to perform the following tasks. 1. Asking question for more information 2. Building blocks 3. Identification of basic colours 4. Awareness of age and name of self 5. Symbolic and thematic kinds of play activities 6. Creative responses 7. Matching three dimensional objects and pictures 8. Imitating adults Visually impaired children have the same potential for cognitive development as non-disabled children during this age.

99%

MATCHING BLOCK 61/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

Construct of World The blind child has limited ability to coordinate and organize elements into higher levels of abstraction, and to verify the information. Therefore, he constructs a reality that is different from the sighted child's. The process of establishing concept- defining attributes and relationships is more problematic for the blind child and less accessible to guidance. The blind child is continually involved in problem solving, but this process, which is essential to future development, is more difficult and less rewarding for him. Object Permanence A stable visual field is the basis of object permanence and other conceptual tasks. Object permanence cannot be obtained by a blind child until he has the ability to reach for objects based on sound cue alone. It is acquired nearly a year later than in sighted children. Causal Relationship Since the results of actions cannot be seen, the blind child may not be motivated to action. He may not understand his ability to cause things to happen or to retain pleasurable stimuli. 87 Constancy Understanding how to align blocks or orient his hands on a page in order to duplicate a pattern will be difficult if he hasn't observed objects in various orientations to know that an object is the same regardless of its position in space. 3.6

Educational needs of the Visually Impaired and Need for Expanded Core Curriculum

for Visually Impaired children 3.6.1. Educational needs for the Visually Impaired Children The challenge for educators of visually impaired children, including those with other disabilities, is how to teach skills that sighted children typically acquire through vision. Visually impaired students have used a variety of methods to learn to read, write, and acquire other skills, both academic and nonacademic. For example, for reading purposes, some students use braille exclusively; others use large print or regular print with or without low vision aids. Still others use a combination of methods, including braille, large print, low vision aids and devices with computer-generated speech, while others have sufficient functional vision to use regular print, although with difficulty. Parents along with other team members are responsible for providing opportunities at various stages to identify variables to be considered and decisions to be made as the challenges increase. As progress is made and children become more responsible, the focus gradually changes to the individual for more involvement in educational and personal decisions. Promoting education for children with visual impairment

- Determine what medium is best for an individual child through the Learning Media Assessment. ●●●● This may be braille, print, dual media, auditory strategies, objects, symbols, or some combination.
- Provide books and literacy tools in a format that is accessible to the child.
- Read aloud using stories and books that are interesting and appropriate for the child.
- Create a literacy-rich environment, in which the child knows that others are reading and writing.

There are a variety of methods that students with visual

88 impairments use to read. Often a single student will use different strategies in particular settings or for specific materials or content. There are six stages in development in which parents and various team members are involved as children's educational development.

1. Infants and Parents, (from Birth to 2 years) Parents are dealing with emotional issues of shock, trauma, and grief associated with the first diagnosis of visual impairment. Confusion and uncertainty cloud their thinking until they can begin to understand and accept the reality of the situation. By then, they need to seek information through support systems, reading and learning what to do. Certified Orientation and Mobility Specialists (COMS) begin to teach infants orientation to touch, sound, and visual objects. They give checklists of activities for parents to follow, and model teaching to reach, learning to sit alone, to crawl, and later to encourage walking. They also teach body parts, body positioning, spatial concepts, and body movements.
2. Preschoolers, (from 2-4 years) This is the stage when a child is striving for independence. Parents (or primary caregivers) are still the primary members of the team. The major decision is to determine who gives the regular care during the day; parents, another family member, or day care. One-on-one teaching of skills and language is a necessity. Preschool teachers begin to be the leaders for learning development and diagnostic assessments and report to parents and therapists. It may best for the student to be placed in a regular classroom with a consulting teacher of students with visual impairments (TVI) or a special classroom, whichever is most appropriate for the child.
3. The Primary Grades, (from 5-7 years) Parents, in consultation with teachers have important decisions to make in regard to placement and instructional service delivery depending upon the child's readiness for and progress in the general and YI-specific expanded core curriculum. The visual status of the child is not the only determinant in placement. At home, the parents are challenged to encourage more independence in personal and home activities. Play opportunities with peers are especially critical as is time with parents to talk about incidents of the day.

89 The Educational Diagnostician is part of the team to develop educational and cognitive measures as indicated, and share assessment data with parents and teachers to develop the individualized educational programme (IEP). 4. Middle to Late Elementary School, (from 8-12 years) The key challenge is to develop the learning scope and efficiency of the students as a priority to make maximum progress possible. Instructional decisions based upon student achievement will determine the type and amount of VI specialized instruction. New skills to be emphasized are keyboarding for the computer and other technology- related instruction. Social skills are important to enhance communication and interaction with peers and teachers, and as a means to effect natural independence as a prelude to middle and high school. 5. Middle School and High School, (from 12 to 18 years) The early and later teen years indicate the need for additional members of the previous teams to ensure a broader scope of academic, vocational and job-seeking considerations. Rehabilitation counselors and/or job coaches, adults with visual impairments as role-models, and extended family members are valuable members of the team. 6. Transition to Adulthood, (from 18 years and beyond) The major decisions center around, i. what now? ii. Where do I live? iii. Where can I work? iv. Should I pursue further education? When an individual has other disabling conditions, these decisions require consultation with team members about the optimal situation for each individual. Some may be unable to live away from home or other protected environments. Creative personal living and working situations, including sheltered or supported employment, may be suitable for those with limited independence. So there are various range of inclusive teaching strategies that can assist all students to learn but there are some specific strategies that are useful in teaching a group which includes students with visual impairments. In considering alternative forms of assessment, equal opportunity, not a guaranteed outcome, is the objective. You are not expected to lower standards to accommodate students with a disability, but rather are required to give them a reasonable opportunity to demonstrate what they have learned. Disability-specific compensatory skills refer to the use of strategies, techniques, and adapted materials that students with visual impairments need to access the general education and common core curricula.

90 BLINDNESS AND ITS IMPLICATION FOR EDUCATION 1) In learning visually disabled Children to perceive an idea through 'structure' rather than 'form' as in the case of sighted children. Therefore, visually disabled children are likely to miss specific information of the learning activities. 2) Visually disabled children may take more time for forming a concept Since the tactile and auditory perception cannot replace visual perception and not even match the experiences formed out of visual perception, visually disabled children tend to attain reduced experiences. 3) The visually disabled child may need to be given direct assistance to learn systematically even the simple skills which sighted children learn almost spontaneously through imitation and contact with the environment. 4) Due to the lack of visual feedback, the visually disabled child may skip a number of intervening steps of an activity which requires more visual orientation. 5) The visually disabled child may have difficulty in forming exact concepts as he has to manipulate from part to whole. 6) The visually disabled child may develop verbal expression without associating proper meaning for that expression. 7) The visually disabled child may show deficiencies in some subjects when he is untaught. Predictions should not be made that he is unteachable. Efforts are necessary to teach him difficult concepts too 8) A misconception that visually disabled children possess extra power in their auditory and tactile ability should be overcome. They need sufficient practice for developing these skills in them. 3.6.2. Need for Expanded Core Curriculum for Visually Impaired Children The expanded core curriculum (ECC) is used to define concepts and skills that often require specialized instruction with students who are blind or visually impaired in order to compensate for decreased opportunities to learn incidentally by observing others. In addition to the general education core curriculum that all students are taught, students with visual impairments, starting at birth, also need instruction in

91 the ECC. The ECC areas include needs that result from the visual impairment that enable the student to be involved in and make progress in the general education curriculum and other educational need that result from the child's disability" The Expanded Core Curriculum, first developed by Halted (1997), defines the concept and skills typically learned incidentally by sighted students that must be sequential presented to the blind students or low vision. Components of the expanded core Curriculum have been adopted as the essential core curriculum for student with visual impairment. These unique curriculum areas need to be included in the personal programme plan. Concept Development Students with blindness need assistance in making the connection between vocabulary and real objects, body movements and abstract ideas. ●●●● Pre-teach vocabulary and key concepts which relate to the curriculum through verbal The explanations and concrete experiences using a multisensory approach. ●●●● Pre-teaching can be provided by someone other than the teacher, such as a peer, an older student, a teacher assistant or a parent. ●●●● After the student has participated in pre-teaching and classroom instruction, it is crucial to review concepts and vocabulary. Organizational Skills ●●●● Organizational skills are an integral part of student success and are essential for the student with blindness. ●●●● Have the student organize, use and take responsibility for his/her personal work space. ●●●●

100%

MATCHING BLOCK 63/112

SA

submission.pdf (D130940981)

Provide the student with a definite place to put things,

with the expectation that the student uses this space. ●●●● Use containers and zippered pencil cases to store objects. ●●●● Use techniques for safely locating and searching for dropped objects. ●●●● Attach braille labels to binders and folders for the student.

92 ●●●● Provide sufficient space for materials and equipment. Often a special room is required for storage and use of specialized equipment. A desk may need to be adapted to provide a larger working area. ●●●● Brailled texts require more storage space and should be stored upright. Communication Listening Skills A student with blindness learns through listening, so it is important that he/ she develops good listening skills. Listening skills are taught as an integral part of the language arts curriculum in the elementary grades and a student with blindness will benefit from these activities. ●●●● Discriminate between different sounds; ●●●● locate the direction of sounds; and ●●●● Associate sounds with objects and situations. Listening and interpreting oral information: ●●●● to listen for sequence; ●●●● to listen for details; ●●●● to listen for main ideas; ●●●● to listen to follow instructions; and ●●●● New vocabulary. Check that the vocabulary is within the student's experience and has meaning. Listening to audiocassettes: ●●●● minimize distractions to increase attending; ●●●● read the questions to be answered before listening to the information; ●●●● listen to the pertinent parts of the tape prior to the lesson; ●●●● play a short portion of the tape, then stop to write notes; and ●●●● adjust the speed of the recorder. Listening to a reader: ●●●● Having someone read to the student has the following advantages:

93 ●●●● the student has immediate access to the same reading material as other students; ●●●● the reader can scan the text to find appropriate material; ●●●● the reader can give information on spelling and punctuation; and ●●●● this is an option when taking tests. Braille Reading Skills The student will require a pre-braille and braille reading program, in addition to participating in the regular reading programme. Writing Skills ●●●● Teach a student who uses braille to write his/her signature. Raised lined paper and signature guides are available. ●●●● Teach keyboarding skills (grade 3 or 4) after the braille writing skills are established. ●●●● Provide access to a computer at an early age. Adaptations may be necessary. ●●●● The student should be able to spell words letter by letter as well as by using braille contractions. Speaking Skills - A student should: ●●●● look directly at the speaker; ●●●● learn to participate in a discussion; ●●●● learn when to speak; ●●●● learn to use and interpret voice modulation; ●●●● learn to initiate and contribute to a conversation; Mathematics Skills There may be a number of gaps in the student's general knowledge that would normally have been gained through visual observation. Math for the student with blindness is prepared in Nemeth code. ●●●● Speed may be improved by adapting or shortening assignments. ●●●● Make or purchase braille flash cards. ●●●● Raised pictures, diagrams and concrete objects are necessary to develop concepts. Simple raised outlines are preferred.

99%

MATCHING BLOCK 64/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

Independent Living Skills This area of the expanded core curriculum is often referred to as "daily living skills." It consists of all the tasks and functions persons perform, in accordance with their abilities, in order to lead lives as independently as possible. These curricular needs are varied, as they include skills in personal hygiene, food preparation, money management, time monitoring, organization, etc. Some independent living skills are addressed in the existing core curriculum, but they often are introduced as splinter skills, appearing in learning material, disappearing, and then re-appearing. This approach will not adequately prepare blind and visually impaired students for adult life. Traditional classes in home economics and family life are not enough to meet the learning needs of most visually impaired students, since they assume a basic level of knowledge, acquired incidentally through vision. The skills and knowledge that sighted students acquire by casually and incidentally observing and interacting with their environment are often difficult, if not impossible, for blind and visually impaired students to learn without direct, sequential instruction by knowledgeable persons. Recreation and Leisure Recreation and leisure

activities will vary with the student's age and functional vision. These activities may range from pretending and playing with toys to artistic abilities and using technology, equipment and tools. Recreation and leisure offer opportunities for students to use their abilities, be active, feel self-worth, release tension, show others what they can do, get along with others and receive recognition or rewards. Many recreation and leisure activities promote lifetime skills that play an important part in developing a satisfactory life. Recreation and leisure activities provide opportunities for students to integrate and apply skills acquired in many curricular areas. Students with blindness need additional encouragement to pursue these activities. The student should develop: ●●●● an awareness of leisure activities and the skills to manage leisure time well; ●●●● skills for solitary play and solitary leisure activities; ●●●● skills for social play and social leisure activities; ●●●● an interest in learning about or joining a community club or group; ●●●● an interest in physical play, physical games, physical fitness and sports; ●●●● an enjoyment of pets and nature; ●●●● an enjoyment of music and dance; ●●●● an interest in a hobby; 95 ●●●● skills for reading, writing, speaking and drama as leisure activities; ●●●● skills for using science and technology for leisure purposes; ●●●● an interest in taking lessons (music, gym, drama, swimming, dance); and ●●●● an interest in attending camps.

97%

MATCHING BLOCK 65/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

Knowledge of the Eye Condition A student needs to understand and be able to tell others comfortably about the cause of his/her

blindness. Understanding of the following leads to acceptance and dealing with the blindness: ●●●● Name, cause, implications and prognosis of the student's eye condition; ●●●● Genetics counseling; ●●●● Eye care and service; and ●●●● Knowledge of factors secondary to the eye condition (diet, medication). Orientation and Mobility Orientation and mobility (O & M) instruction prepares a student with visual impairment to travel independently and safely. Orientation skills help a student to be aware of his/her own body in space and the surrounding environment. Mobility skills are specific techniques used to enable a student to move easily from one place to another. Orientation and mobility includes both mental orientation and physical locomotion. Orientation and mobility skills contribute to development in social skills, mental and physical interactions and the general well-being of the student. These skills are needed for the student with low vision as well as the student with blindness.

98%

MATCHING BLOCK 66/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

As a part of the expanded core curriculum, orientation and mobility is a vital area of learning. Teachers who have been specifically prepared to teach orientation and mobility to blind and visually impaired learners are necessary in the delivery of this curriculum. Students will need to learn about themselves and the environment in which they move - from basic body image to independent travel in rural areas and busy cities. The existing core curriculum does not include provision for this instruction. It has been said that the two primary effects of blindness on the individual are communication and locomotion. The expanded core curriculum must include emphasis on the fundamental need and basic right of visually impaired persons to travel as independently as possible, enjoying and learning from the environment through which they are passing to the greatest extent possible. 96

Orientation & Mobility should be incorporated into the student's Programme and timetable. An individual program is determined by considering the following factors: ●●●● diagnosis and degree of visual impairment; ●●●● prognosis of visual impairment; ●●●● functional vision; ●●●● presence of other disabilities; ●●●● age; ●●●● cognitive functioning; ●●●● general health; ●●●● school and community environment; and ●●●● family, school and community resources.

SEVI-31 with glossary for alignment.docx (D127037367)

Technology Technology is a tool to unlock learning and expand the horizons of students. It is not, in reality, a curriculum area. However, it is added to the expanded core curriculum because technology occupies a special place in the education of blind and visually impaired students. Technology can be a great equalizer. For the braille user, it allows the student to provide feedback to teachers by first producing material in braille for personal use, and then in print for the teacher, classmates, and parents. It gives blind persons the capability of storing and retrieving information. It brings the gift of a library under the fingertips of the visually impaired person. Technology enhances communication and learning, as well as expands the world of blind and visually impaired persons in many significant ways. Thus, technology is a tool to master, and is essential as a part of the expanded core curriculum.

Career Education There is a need for general vocational education, as offered in the traditional core curriculum, as well as the need for career education offered specifically for visually impaired students. Many of the skills and knowledge offered to all students through vocational education can be of value to visually impaired students. They will not be sufficient, however, to prepare students for adult life, since such instruction assumes a basic knowledge of the world of work based on prior visual experiences. Career education in an expanded core curriculum will provide the visually impaired learner of all ages with the opportunity to learn first-hand the work done by the bank teller, the gardener, the social worker, the artist, etc. It will provide the student opportunities to explore strengths and interests in a systematic, well-planned manner. Once more, the disadvantage facing the visually impaired learner is the lack of information about work and jobs that the sighted student acquires by observation. Because unemployment and underemployment have been the leading problem facing adult visually impaired persons, this portion of the expanded core curriculum is vital to students, and should be part of the expanded curriculum for even the youngest of these individuals.

Self Concept and Socialization Social and life skills that other students can learn naturally through observing others and modeling, must be taught specifically to the student with blindness. aaaa Teach the student to turn and face the speaker. aaaa A student with blindness may have mannerisms, such as rocking or repeatedly 98 rubbing the eyes. Such mannerisms can interfere with social interactions. This is a sensitive issue; professional advice should be sought. aaaa Encourage the student to initiate a conversation or play activity. The student will often wait silently until someone else takes the initiative. aaaa Help the student to understand and respect the personal space of others. The student will also need to be able to ask others, in a courteous way, to respect his or her personal space. Social interaction skills needed to respond appropriately and participate actively in social situations, such as: ●●●● shaking hands ●●●● turning toward others when speaking or being spoken to ●●●● using language to make a request, decline assistance, or express a need ●●●● expressing emotion and affection appropriately ●●●● participating appropriately in conversations in various situations 3.7.

Low Vision Students with low vision exhibit a wide range of visual impairment. Teachers should be aware

of

97%

MATCHING BLOCK 73/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

that no two students with low vision have the same functional vision. Even if they are diagnosed as having the same eye condition and similar acuity. Vision may fluctuate and be influenced by such factors as fatigue, light glare, lighting conditions and time of day. Therefore special attention must be given in assessing the needs of the students with low vision

and A 1 education of them requires unique strategies.

Definition of low vision : "Persons with low vision" in the PWD act means persons

100%

MATCHING BLOCK 71/112

W

with impairment of visual functioning even after treatment or standard refractive correction but who uses or is potentially capable of using vision for the planning or execution of a task with appropriate assistive device. 99 The

points to be emphasized from the definition of low vision are: ●●●● There is significantly reduced vision. ●●●● This can affect the performance. ●●●● The vision can be used for various purposes including reading. ●●●● There is need for assistive devices. ●●●● Assessment has to be made of the distance and near visual acuity and other visual functions such as contrast, light sensitivity, colour vision and visual field. Difference between blindness and low vision: a) Blindness can be defined as having no vision or no significant usual vision while low vision involved significant usable residual vision. b) Blindness mean visual acuity of less than 3/60 and

78%

MATCHING BLOCK 74/112

Rajesh E- TEXTBOOK ON BASICS OF VISUAL IMPAIRM ...
(D143341256)

low vision means visual acuity of less than 6/18 but equals to or better than 3/60.

Some of the characteristics of low vision children that are important for a teacher to know are : Ø Limited opportunities for incidental learning. Ø Limitation in the range and variety of experience. Ø Limitation in the ability to get around. Ø Limitation in interaction with the environment. Specific implications of low vision For each person it is necessary to ●●●● Determine the activities normally done by the person with low vision and other people in the same community and what visual skills are required to carry these out. This may be at school, in the village, or at work. The person should be assessed in a place appropriate for those tasks. ●●●● Analyze the visual elements of a task so that the task can be modified and the environment adapted to the special equipment used ●●●● Observe the visual environment and assess/observe the person under different environmental conditions. Vary aspects of the environment also, e.g. distance from the task, lighting, contrast, colour and time allowed.

100 ●●●● Determine which sense is the most efficient for a particular task. For example, vision, enhanced vision, auditory, tactual, or some combination of these senses. In order for students with low vision to achieve high levels of academic and social success, the following recommendations must be incorporated into the educational program:/for these students. Families, teachers, and students need to recognize the unique skills that students who have low vision must be taught and maintained throughout their formal education. 1. Students with low vision must be given opportunities by teachers and family members to understand and communicate their visual impairment and their visual needs to others. Beginning in the preschool years on, it is incumbent that professionals and families work together to assist students who have low vision to understand and to communicate their vision needs in a straight- forward manner to their teachers, peers, and members of the community. Initially students should be able to identify the name of their visual impairment. As students mature and gain more social competence, they must be able to explain their visual impairment to others. Students should also be able to communicate their needs resulting from visual impairment in a succinct and straight-forward manner, given their age and developmental levels. 2. Students with low vision must receive guidance in strategies to promote effective interactions in a variety of social situations. This is especially important for students with low vision who have additional disabilities. Strategies and curricula must be provided to help students with low vision to become more socially competent in the following areas: ●●●● Developing effective interaction skills that include social initiations, turn taking, gaining entry into a group, using auditory cues to assist with the interpretation of body language. ●●●● Learning to use a combination of senses to help support and interpret social encounters with peers, family members, and co-workers. ●●●● Asking for assistance when needed in social situations. ●●●● learning effective communication techniques to promote confidence in a range of situations ●●●● Providing opportunities for the students with low vision to practice communicating A I their needs and concerns with family members in a safe, nurturing environment.

101 3. Students with low vision need guidance to develop strategies to promote self-advocacy skills in schools, communities, and vocational settings. Students with low vision, including those with multiple disabilities, need to be able to ask for assistance, and make their needs known in a clear and socially-acceptable manner. Teachers, families, and other professionals can support students in this area by providing the following opportunities: ●●●● Meeting and interacting with role models who have similar visual impairments. ●●●● Engaging in consumer-related activities through organizations such as the All India Council of the Blind, the National Federation of the Blind, and the National Association for the Blind. ●●●● engaging in role play situations in which the need to use self-advocacy skills, such as asking for front row seating at a concert, or the opportunities to use low vision devices in school situations. ●●●● Providing information regarding modifications for accessible materials and clinical low vision evaluations. ●●●● Providing direction and advice in a range of real life experiences where students can learn to cope with a variety of independent activities. ●●●● Providing effective strategies to ask for assistance from others. ●●●● Learning strategies to promote positive social relationships in work situations. ●●●● Encouraging families to provide safe situations in which students must advocate for themselves. 4. Students with low vision must be supported in establishing an identity that is unique to themselves that is neither as a blind individual or an individual who is sighted. Ongoing support is required for students whose vision loss is progressive and who may eventually require sight substitution techniques. It is essential that students who are low vision have an identity that is their own. Identifying oneself as low vision should not be viewed as a negative, but rather as a unique part of the student as an individual entity. Promoting oneself as an individual with low vision enhances social and emotional stability. The following strategies may help to support the importance of establishing a strong identity as a person with low vision: ●●●● Engaging in activities that promote a positive self-image by having students identify their strong attributes.

102 ●●●● Providing opportunities for the students with low vision to enhance their physical appearance through the selection of clothing, use of make-up, use of attractive low vision devices, and by learning strategies to improve body stance and posture, gestures, and facial expressions. ●●●● Providing experiences that allow students with low vision to discuss their visual impairment with peers and trusted adults in a safe and nurturing environment. ●●●● Providing experiences that allow students with low vision to excel and to demonstrate specialized skills or strengths. ●●●● Allowing students who are low vision to feel comfortable with identifying themselves as a person with low vision, and promoting their status as an attribute. ●●●● Providing opportunities for students with low vision to discuss strategies for disclosing their visual impairment to others. ●●●● Providing experiences for students with low vision to drive, and to develop strategies for non-driving. ●●●● Encouraging families to provide opportunities in the home environment for students to take responsibility for chores, homework assignments or projects, and personal belongings. 3.7.2 The needs of people with low vision This includes individuals trying out different optical and electronic aids in their home environment. The challenge is in finding the right balance between visual performance, comfort and aesthetics so that people can easily and happily integrate the right solution for them in their daily life. Lighting Lighting is one of the most important and simple aids. One of the key aspects of any low vision assessment is to check the lighting to ensure there is the right lighting and it is positioned correctly. Some types of light will work better than others depending upon the eye disease. Having good lighting while reading, writing or undertaking fine work is very important; it can make a huge difference to the ability to see the task being undertaken.

103 Talking aids: There is a large range of talking aids available including talking scales, timers, clocks, watches, calculators, good thermometers, key chain alarms, key ring voice memo devices, vibrating and beeping liquid level indicators and talking colour detectors. Large Print Books: Large print books are usually printed in 16 or 18 point font and this can be a good option if sight allows for this level of print size. A selection may be available from the local library or a low vision service to borrow or purchase. Reading: Reading guides are simple devices that enable better focus when reading either normal or large print. They are simple black cards or sheets with a block cut into them to guide the writer or reader. Reading stands and lap desks with built in lighting can help with correct positioning while reading. Writing : There are a number of writing aids available including large print or tactile address books, diaries, organizers and notebooks along with: ●●●● Writing frames or simple rail line guides, available in various formats including envelopes guides and signature guides, raised line or bold writing paper ●●●● A range of thick felt tip pens Optical Magnifiers: There is a large range of optical magnifiers in different magnification strengths and sizes. The more powerful magnifiers are smaller, and need to be held close to the eye when being used. ●●●● Hand-held magnifiers, some with built-in lighting ●●●● Bar magnifiers that can magnify one line of writing at a time ●●●● Dome magnifiers which many find easier to use ●●●● Fixed stand magnifiers which keep your hands free for reading, writing and

104 other activities such as signing a cheque. ●●●●● Spectacle binoculars available in clear or tinted colour for reading or close detail work. Primary Aids : Canes Many people with low vision may never need or use a cane but it can be very useful for negotiating the environment. Many people find that a cane gives them much greater confidence to move about. Technologies Audio Books Audio books or talking books are available from a range of providers including low vision agencies, council libraries and audio book websites. Some local newspapers are also available in audio format. Television To help with TV viewing there are large screen televisions and universal remote controls with large buttons. Electronic magnifiers Electronic magnifiers are excellent for high magnification reading and writing to support a wide range of daily living Computers There is a range of ways to assist those with low vision to use a computer including a large screen to increase the viewing area and ways to increase the size of items on the screen. For those with low vision, simple fonts without decorative curves are easier to read (eg Arial or Calibri) and use upper and lower case instead of typing in all capitals. Also, when typing, try to add extra spacing between words and lines of text so the breakdown of sentences and paragraphs is clearer. Close Circuit Television (CCTV): An electronics projection magnifier that enlarges reading materials by projecting on the screen. Talking

SA CHAPTER II review with aiignment.doc (D15199607)

Screen Reader/Speech Synthesizer Screen readers provide auditory feedback when using the keyboard as well as auditory access to information displayed on the monitor. These systems consist of a software programmes and speech synthesizer. The software programmes sends information from the computer to the synthesizer, where phonemmes are combined into words and the words are spoken. Most systems allow choices in volume, voice quality and speed of output. Students with limited vision will find these devices useful, especially when connected to a regular printer for output (JAWS, Intellitalk, IBM ScreenReader/DOS). Voice Access Voice access systems allow the user to interact with the computer screen by using voice commands instead of the keyboard. They are particularly useful for students who have difficulties with fine motor control as well as visual impairments. These systems include special software and sound cards to allow for voice output of information on the screen. As with screen readers, they can be connected to braille and regular printers for output (DragonDictate, Naturally Speaking). Scanner The scanner will scan print text of good quality. It must be used in conjunction with optical character recognition software. Then the scanned text can be

saved to be printed in braille or accessed through a speech synthesizer.

Glossary Assessment: A procedure to determine self-sufficiency of low vision involving functional and clinical measurements. Braille: A tactile method of reading and writing, generally used by the blind. It involves combinations of six raised dots punched into paper, which can be read with fingertips. Cane: A mobility aid that helps in knowing the obstacles while the person is moving. Close Circuit Television (CCTV) - An electronic magnifier that enlarges reading material by projecting on the screen. Disability: Results from a loss of physical functioning or difficulties in learning and social adjustment that significantly interferes with growth and development. Field of Vision: defects of degree of an angle that a person can see without turning his/her head or moving the eyes. includes the limits of peripheral sight or that which lies to the sides of straight ahead Filters: Illumination control device used to provide excellent protection from glare. They can be used with most optical aids systems. Functional Vision: the level and use of residual vision to cope up with requirement of daily life. Handicap: Refers to a disadvantage imposed by the environment and the person's capacity to cope up with the disadvantage.

108 Impairment: Refers to identifiable defect in the function of the organ. Subject of medical profession. Individualized Educational Plan (IEP): - An educational plan tailored to an individual students needs. Magnifiers: Use of deep plus lens to magnify small objects so that they can be seen more easily. Non-Optical Aids: Aids used to enhance vision through non-optical means, for example illumination, contrast etc. Ophthalmologist: Medical personnel involved in examining a person with visual impairment and prescribing medical treatment. Optical Aids: Lenses placed between an eye and an object to alter the retinal image of the object. Orientation: Understanding of one's own relative position in space that restricts movement. Pinhole Aperture: A device to control illumination. Placing it before an eye reduce blur. Retina: Neural tissue that sends impulses to the cortex (brain) via the optic nerve for visual perception. Tactile Clues: Learning about various objects in the environment through the sense of touch. Tracking: Concentrate .following of the objects with eyes. Typoscopes: A piece of black cardboard with a slit in it, to block out all but the line of print view while reading. 3.8 "Check your Progress" I. Choose the correct response 1. The ability to locate one self in one's environment is known as a) Orientation. b) Daily living activities.

109 c) Sensory training. d) Mobility. 2. The ability to move in the environment from one place to another is called as a) Orientation. b) Daily living activity. c) Sensory training. d) Mobility. 3. Introduction of daily living skills to a visually impaired child depends on the assessment of his : a) Social achievements. b) Maturity level. c) Independent mobility. d) All the above. 4. Language development mainly depends on a) Understanding of syntax b) Ability to hear to sound properly c) Reading great classics d) Proper attention 5. 'Verbalism' develops in visual impaired children due to a) Poor vocabulary. b) Good vocabulary. c) Lak of personal direct experience. d) Misunderstanding word meaning. 6. Communication with the blind child in the initial years must be through a) Dialogue b) Imitation

110 c) Facial expression d) Direct physical contact 7. Stereo type attitude means a) Conventional behaviour b) Unhealthy behaviour c) Aggressive feeling d) Favourable towards blindness 8. Reduction in the range and variety of experiences a) Is a subjective effect of blindness b) Is an objective effect of blindness c) Is impersonal loss of visual impaired children d) Reduction in experience provided to children II. State true or false for each of the following statements 1. Blind persons do not have to learn special technique for all the activities of the daily living. 2. 'Orientation mobility' is essential for independent living of the visual impaired persons. 2. Senses are the gateway to knowledge. Hence the effects of blindness are not basically cognitive. 4. All blind are special talent like musical talent and fantastic memory. 5. Although blind children may have delayed physical development due to their inability to do some physical activities, they typically do not differ in physical ability from normally seeing children. III Answer the following questions 1 Observe any six manneristic behaviours which are found in visually impaired children and investigate why such behaviours are present in them? 2 Verbalism is mostly found in V.I.C. Investigate why such behaviour present in them?

111 3 Compare the concept development skills of non-disabled children and visually impaired children with additional disabilities? 4 Identify one object in your surrounding, which you find that a visually impaired child differently and modify it to his needs. 5 Discuss with five visually impaired to find out the extent of their social and emotional development. 6 Prepare a case study of a visually impaired child's language development processes. 7 Anita lives in a urban slum area. She was detected with central vision loss at birth. Discuss how his psychological development will be affected. 3.9 Let us Sum up ●●●●● The societies, across the globe have developed their own images of blind persons, of their capabilities and of their limitations. Even beyond that, they have developed their own ways of coping with the capabilities and/or limitations of the blind. ●●●●● All low vision children are different from each other and their functioning level depend on what area of their visual system is damaged. ●●●●● Presence of just one or two symptoms does not indicate low vision. ●●●●● Verbalism and word-mindedness is reported to be exhibited by the visually impaired children due to absence of sight. ●●●●● Visually impaired children may experience developmental delays in acquiring concepts because of their visual loss. ●●●●● Low vision children with additional disabilities have more learning problems and psychological problems as well. ●●●●● The doctor has to indicate whether the vision will deteriorate further or remain as such. The decision to learn braille, use of magnifiers in some cases or reading prints can also depend on this. ●●●●● Children's with peripheral vision can read and write but may find moving about difficult.

112 ●●●●● Whether a child with low vision enters adulthood with an inferiority complex or with a positive self-concept depends on his/her teacher, parents and other significant people in his life. The child should be treated normally like any other child except for having special needs. ●●●●● No one educational plan is beneficial for all low vision persons. ●●●●● Each individual child has to be comprehensively assessed. ●●●●● Cognitive development is the result of sensory development, perceptual development in the way in which the child interprets sensory impulses received by him, as well as the ability to form concepts, exercise judgment, reason and solve problems. ●●●●● Development of proper mannerism contributes to the social integration of the visually disabled child. Unwanted mannerisms of visually disabled children could be controlled through timely invention and substitute activities. 3.10 Reference ●●●●● Bishop, V.E. Teaching the Visually Limited Child. The children with visual problems can be identified with some simple techniques; Vision may be improved with spectacles, treatment or operation. Early intervention services have significant impact on improving visual functioning of the visually impaired infants and toddlers. Thus, it is important to identify children who have impaired vision at an appropriate time. The identification of these children must be carried out on the basis of objective assessment of the eye condition and visual functioning. This assessment provides information regarding a student's ability to use his vision within the learning environment. In this unit we shall discuss the meaning, need and importance of clinical and functional assessment procedures – attention, tracking, visual closure visual background, from constancy, eye- hand coordination and eye-foot coordination and the activities to improve the visual efficiencies. The report on the "Global initiative for the elimination of avoidable blindness by the World Health Organization" documents that there are 8.9 million blind people in India. The definition of Low Vision defined by WHO-ICEVH conference on the "Management of the

89%

MATCHING BLOCK 92/112

SA

komathi thesis.new.docx (D123569702)

Low Vision in children is: A person with low vision is one who has impairment of visual functioning even after treatment or standard refractive correction and has a visual acuity of less than 6/18 to light perception, or a visual field of less than 10° from the point of fixation, but who uses, or is potentially able to use vision for planning and / or execution of a task."

This is a functional / working definition of low vision. It recognizes that people with limited amount of vision are low vision. While the educational service for blind persons in India is more than 100 years old, the education of low vision is of recent origin. In the 1980s, education of low vision was provided with non-visual methods. In this unit, we shall analyze the maximum use of remaining vision to increase the visual efficiency that all children and adult get the greatest benefits from whatever sight they have. In this unit, we shall analyze the concept of clinical

116 evaluation, functional vision, visual efficiency and activities to promote visual efficiency etc. The Importance of early identification and intervention, clinical assessment, activities for functional assessment and the use of adapted tests for assessment are discussed in this unit. Vision is responsible for 80 to 90% of what a child learns during the first six years of life. A child uses vision in real life situations and these real life situations are the environments which promote his/ her growth and development. Functional vision refers to an individual's ability to use his/her vision in the everyday tasks of real life, such as reading, doing house work, getting around place to place. A functional vision assessment measures how well a child uses his/her vision to perform routine tasks in different places and with different materials throughout the day. This information gathered in the assessment enables the Low Vision teacher and the parent/ caretaker to develop an educational programme which will further enhance the development of functional vision. The assessment of functional vision aims to determine:

- What people see
- How they can see and use their vision
- Under what conditions they can see

The information can be used to understand why people can or cannot do particular activities. The purpose is to provide information about the use of vision plan training to enhance visual skills. A functional vision assessment is conducted by rehabilitation professional –a low vision specialist, or a teacher who is specially trained in low vision; Information about how the child uses his / her vision is gathered from parents/caregivers and other teachers who know the child well. Specialist will review records and may talk to the eye doctor to learn more about the child's visual condition. Functional Assessment can be done at various places and with a variety of materials. It is crucial to assess the child in everyday setting at home (indoors and outdoors); school(in the classroom or playground); or in the community, doing his/her usual activities and tasks. The low vision specialist will observe the child in his/her usual surroundings to learn how the child uses vision. It is essential to evaluate the child's effective use of vision

117 Factors that affect how well a person sees

- Visual Acuity
- Visual Field
- Control of eye movements
- Light
- Colour
- Contrast
- Duration and severity of low vision
- Use of low vision at an early age/ visual experience
- Intelligence

* What is Functional Vision? Functional vision is the use of vision for particular activities. Functional visual skills are required to carry out every day activities.

4.2 Objectives After studying this unit, the learners will be able to:

- Identify the children with visual problems
- Define and describe the need and importance of intervention
- Understand the importance of clinical assessment
- Distinguish "clinical evaluation" from " functional vision"
- Describe visual efficiency and suggest activities to promote visual efficiency to the visually impaired person;
- Explain the optical and non-optical devices that are used to increase visual function
- Suggest activities to promote visual efficiency training programme for the visually impaired person;
- Identify the useful activities to improve eye hand coordination and eye foot coordination;
- State the importance of guidance and counselling to promote visual efficiency training programme

118 • Use commonly adapted tests for visual assessment • Carry out functional assessment to low vision children. After studying this unit the students will be able to learn :— • What is functional assessment of vision. • How the assessment of functional vision aims to determine. — What people see — How they can see and use their vision. — Under what conditions they can see. • Factors that effect how well a person sees. 4.3 Interpretation of clinical assessment of vision

4.3.1 Importance of Early Identification and Intervention: Child development research has established that the rate of human learning and development is most rapid in the infant and toddler stage. Neglect of appropriate eye check-up of children reporting eye problems runs the risk of damaging the vision of children who otherwise can be helped to make the best use of their remaining vision. This will also run the risk of missing an opportunity to learn during a state of maximum readiness. Karnes and Lee (1978) have noted that only through early identification and appropriate programming can children develop their potential. Children with low vision experience challenges in playing communicating, interaction, learning, problem-solving skills, and performing in daily routines and activities. Early intervention plays a significant role in preventing and reducing the extent of developmental delays. Early intervention applies to children of school age or younger who are discovered to have or be at risk of developing handicapping condition. These children can be helped in overcoming their difficulties by appropriate provision of services for the purpose of lessening the effects of the condition. Early intervention is a part and parcel of total rehabilitation process. It is individual based. It aims to help attain independence in children with special needs resulting from low vision condition. Early intervention can be remedial or preventive or remedying the existing developmental problems or preventing their occurrence. Early intervention focuses on the child alone or the child and the family together. It could be centre-based, 119 home based, hospital based or a combination of these. Early intervention may begin at any time between birth and school age. There are three primary reasons for initiating early intervention. They are: 1. To enhance the child's development 2. To provide support and assistance to the family 3. To maximize the child's and family benefit to the society. 4.3.2. Tools for Low Vision Assessment The tools for low vision assessment are long handled occluders, Janelli's and Halberg clips, printer, trial lens holder, clip-on pin-hole, universal and paediatric trial frames, Jackson's cylinders up to 2 diopters, ruler and torch. The tools also include a full aperture trial lens set and a good range of auxiliary lenses like Stenopic slit, red green filters, prisms, etc. These may include Snellen's, ETDRS LogMar, Sloan's Letter, Lea's symbols, VA Tester, Lea's preferential looking paddles, paediatric low vision test, Fienbloom distance test, Bailey-Hall Cereal test. Other tests include brightness acuity test for glare assessment. Panel D15 for quantitative colour vision assessment, Lea's low contrast symbol test for contrast sensitivity assessment, Amsler chart manual for central visual field assessment and Ishihara test for colour blindness. Following is the routine for a low vision examination. Steps of Low Vision Assessment 3 Steps: 1. Clinical Evaluation 2. Functional Evaluation 3. Vision Rehabilitation It involves a complete understanding of the condition, its symptoms and concluding the management of the low vision patient. Careful observation of the client's behaviour and his physical status can provide an insight to the severity of the problem. Importance of Diagnosis: the clinical team is primarily responsible for diagnosing the low vision client accurately as the functional implications of the cause of low vision is different in each eye disorder. The areas of intervention are specific to certain eye 120 disorders. Similarly, the age and the status of the eye disorder, whether progressive and non progressive also has a bearing on the interventions planned for the low vision client. 4.3.3 Clinical Low Vision Assessment: A. Observation Patients can be observed as they enter the room to see whether they walk unaided or are supported, whether they feel for a handrail or easily recognize open doorways. Wearing dark spectacle lenses or holding the head down may imply sensitivity to light, although this head position could be due to arthritis. Other things to look for are difficulty in holding things or, tremor. Many elderly low vision patients may attend with a care taker or relative. To summarize observe the following : 1. Mobility 2. Fixation 3. Posture 4. Psychology of patient • Ready to accept the services • Motivated/ depressed B. Interview and History Taking Interviewing is important in order to understand the emotional status and individual needs of the client. The interview also works as a platform for developing a rapport between the examiner and the client. The interview starts with the case history with emphasis on the visual problem. This is followed by the individual's personal history that includes occupation, education, living status and specific functional aspects, like independence, orientation, mobility and activities of daily routine. The daily routine of the client can identify the needs of the individual and areas where help may be needed. Brining to focus activities that may be possible can help in narrowing down the objectives of the client. All the data from the interview have to be recorded in an organized manner so it could be used effectively in finding the solutions. History taking is one of the most important aspects of any low vision evaluation It is critical for the development of appropriate and realistic evaluation and management strategies. Following points should be covered.

121 * General Information • Demographic Information • Interaction between the patient and the accompanying family member • Marital Status/ Living Situation * Ocular History • Ocular history correlates the onset of specific visual complaints with disease appearance, progression or treatment • Diagnosis and onset of symptoms • Past, current, or planned surgeries or treatments • Stability of vision • Family history of eye disease • Previous history of eye disease or vision problem • Current or previous use of spectacles, contact lenses, or low vision aids • Patient's understanding of vision condition and implications for functioning • Virtually, very ophthalmic intervention has functional consequences * Systemic History • Many systemic illness have direct ophthalmic effects, one of the most obvious being Diabetes. • General health review • Current medications • Hearing impairment or other handicapping conditions • Self- care needs (e.g., ileostomy, diabetes) • Orthopaedic handicaps • Psychology considerations (e.g., denial, depression, co-dependency, or suicidal tendencies) • Activities critical to manage are:- * Educational or Vocational Status • School requirements 122 • Seeing blackboard • Computers • Reading Instrument • Retired • On leave from work due to low vision • Homemaker • Has the client considered retiring or resigning because of the vision • Social activities hampering * Financial Status • It's important to understand the commitment to the device • Basic needs of the client • Affordability of the device * Task Related History • It is most important as it provides insight into day-to-day problems that the patient faces. Task –related history should also focus towards the occupation of the patient. It helps the practitioner to understand the basic requirement of the patient. • Visual tasks can be divided into * Lighting Situation We also need to check the lighting situation to understand the patient's problem whether he is able to tolerate sunlight, having difficulty in seeing in dim light, Whether any difficulty in going from bright to dim light. Whether comfortable with sunglasses or requires more bright light(incandescent or fluorescent.) Depending on patient's needs one's recommendation can differ from patient- to patient. It helps you to recognize patient potential as well as limitations and suggests possible interventions. C. Visual Acuity Measurement of visual acuity is one component of the evaluation that allows one to quantify the degree of high-contrast vision loss and, in many cases, clearly identifies 123 the patient's visual impairment as it relates to the chief complaint. Measuring visual acuity also allows the clinician to:

- Help determine best corrected visual acuity (BCVA) • Monitor the effect of, stability and progression of the treatment of a disease • Assess eccentric viewing postures and skills cases, afford the patient an opportunity to experience process • Furthermore, the result of visual acuity testing are the basis for determining initial magnification requirements and the potential for specific rehabilitation strategies. Estimate the dioptric power of optical aids necessary for reading regular print size • Verify the person's eligibility for tasks such as driving • Classify patients as "legally blind" for the purposes of government, insurance and other benefits of exemptions • The methods of assessing distance and near visual acuity in visual acuity in visually impaired patients may be modified to address specific concerns. C.1- Visual Acuity Assessment (Distance) The visual acuity assessment begins with determining the distance acuity of the patient. The procedure involves showing the patient large size numbers on sheets from a particular distance and asking him or her to identify them. Optotypes, single –letter chart gratings and crowded letters of different size may be shown to the patient alternatively. The same procedure is repeated for each eye individually also. 1. Traditional methods of testing acuity are not practical for low vision patients. 2. Vision charts designed for low vision are hand held or movable rather than fixed or projected. Each line contains several characters so memorization is less likely 3. ETDRS charts are recommended for more accurate recording. 4. Patients feel more confident when they are able to read more letters and the start of low vision is with a positive note. 5. The hand held charts avoid glare, give better contrast and can be moved closer so that letter size is doubled

124 6. Changing testing distance requires recalculation of acuity. 7. All patients should be examined first in daylight condition 8. Special charts with grey background should be used in patients with glare problems 9. Bailey & Lovie charts are the logarithmic scale. Main advantage of chart is that it's near vision equivalent; greatly simplify the process of calculating the estimated magnification required by a patient. 10. Log MAR chart- ETDRS uses sloan optotype. Essentially it is same design as Bailey Lovie charts but differ in actual letters used. * LogMAR Charts • Principle of a LogMAR chart is that it uses a logarithmic scale. LogMAR means Log Minimum angle of Resolution • Ian Bailey and Jan Lovie first to incorporate a log scale which has stepwise changes • Calculation of required magnification easy • Five letters per line. There is constant size progression ratio of 5/4 and line is 1.25 X bigger/ smaller than previous * Advantage of a LogMAR chart: Design feature and advantages 1. Equal number of optotypes per line and allows the use of single –letter scoring which reduces test-retest variability 2. Equal logarithmic interval between lines 3. Equal average legibility for each line. It ensures that letter size is the sole determinant of difficulty on a given line 4. Consistent spacing between letters and line i.e..proportional inter-letter and inter- line spacing 5. Geometric progression of letter sizes and allows testing distance to be variable. Vision recording is done at 4m to 2m to 1m. Correction factor of 0.3 should be added to the Log score when the distance is halved.

125 F N P R Z E Z H P V D P N F R R D F U V U R Z V H H N V R D U P R N H Z X V O P R U A D T A T X Z O * Pinhole Acuity Assessment Pinhole acuity test is used to assess the presence or absence of a refractive error improvement in vision and whether indicates that the person may benefit from refractive correction. * Low Contrast Visual Acuity 1. The vast majority of our visual interaction with the world involves resolving low contrast details. Variation in contrast in everyday tasks is undertaken by all patients. 2. Bailey- Lovie low contrast chart, Pelli Robson charts; symbol charts- Lea's symbol charts, hiding Heidi charts with smiling faces to measure low contrast acuity. 3. When optotype based letter charts are used for assessing contrast sensitivity, patient should be given enough time to recognize the letters (temporal summation)

126 4. Practical relevance of low vision contrast visual acuity is that it helps the patient for better understanding of the nature of their visual impairment. 5. Patients feel relieved to see a clinical test that equates to their experience. C.2-Near Acuity Assessment In this step the patient identifies or reads certain typeset of a smaller size from a nearer distance. The distance is accurately recorded. The typeset size is denoted in M units. Reading acuity is the patient's ability to read a more congested and complex typeset prints from a measured distance. Near Vision Testing 1. In low vision near vision is recorded as the size of print that can be read fluently and easily. 2. Perform near vision at two distance allow the patient to read at his/ her preferred distance. Measure the distance 3. Secondly measure functional reading ability for each eye at 40 cms. 4. For both near testing situation use reading cards specifically designed for low vision. 5. It is imperative to undertake near vision assessment only after having completed an accurate refraction and having determined optimal distance vision, low contrast vision, contrast sensitivity measurements. 6. Use M System along with testing distance for recording visual acuity. Discrepancy of more than two M units between the two eyes when tested at same distance, in this case better seeing Eye alone can be corrected by low vision aids. 7. Record near acuity as fraction – the reading distance in cms is the numerator. The print size in M units is denominator eg. 40/4m 8. Use single character visual acuity 9. Evaluate word recognition abilities. 10. Measure continuous text visual acuity. Graded continuous text materials will provide a more accurate measure of reading ability than single optotype measures and are recommended for evaluation of performance with reading devices.

127 11. Assess effects of illumination. 12. Use appropriate vision charts (Lighthouse near acuity chart, near ETDRS chart, LVRC, Sloan M series charts- these are calibrated in meter equivalents (M Units); and these simplify calculation of magnification. 13. Final determination and prescription of low vision device should be based on performance (i.e., reading actual printed materials such as newspaper and labels not printed acuity charts.) 4.4 Functional Assessment of Vision : Concept, need and methods 4.4.1 Concept Functional vision is the ability to use vision to perform desired tasks. Because of impairment in the eye and other parts of the system, low- vision children will not learn visually without intervention and help. Selection of instructional programmes and techniques requires a thorough assessment and understanding of the child's capabilities. This is mostly done by the educators. In vision evaluation procedures, there are two levels- the screening and grouping of children with different degrees of impairment, and assessment of the disability of the child. The children can be classified into several groups: those with Light perception Light perception without projection Visual acuity less than 3/60 Visual acuity 3/60-6/24 The children are assessed for visual disability- Dr Jill Keeffe's procedure of screening for impaired vision can be adopted. The assessment is done for distance visual acuity, near vision, visual field, contrast sensitivity, and colour vision. The functional vision skills of individuals are also assessed. The functional assessment explores how the child uses vision, at what distance he/she sees object, at what distance certain size symbols can be read, the visual language understood by the child and other educationally and related skills. Observation should be made to determine the technique that the child presently uses in communication, orientation, mobility and daily living skills.

128 After assessment, a training programme should be planned. The training programme includes appropriate sequential visual stimulation activity which would help the child to enhance visual efficiency. 4.4.2 Need for Assessment of Functional Vision This assessment provides information regarding a student's ability to use his vision within the learning environment. It includes acuity, colour, field and environmental accommodations. It will include a list of recommendations for modification and adaptations of instructional materials. The clinical evaluation of a student with visual impairment does not always reflect the student's true visual abilities. It is the responsibility of teachers of visually impaired to gather assessment data of a student's functional vision, it is recommended that materials be used with which the student is already familiar and which are at the student's current level of functioning. The activities used for the functional vision assessment should be drawn from a variety of task, i.e. academic, non-academic, extracurricular, and special context. In addition to the visual functioning information, information should be gathered from parents and the staff involved with the students. A functional vision assessment tends to be subjective; therefore, care must be taken into account. Children develop visual skills at different rates. The specific nature of visual impairment will influence the rate and level of achievement. In other words, visual functioning is related in part to the condition of the eye or the structure of impairment. The use of

50% MATCHING BLOCK 94/112

SA

Rajesh E- TEXTBOOK ON BASICS OF VISUAL IMPAIRM ... (D143341256)

functional vision may be improved with training. Many children can learn to make better use of their residual vision and can function effectively with only small amount of visual information. Objects and print can be recognized even when they are blurry or even if only parts of them

can be seen. * Aim of the Assessment of Visual Functioning • To Determine current visual functioning level of the child/ adult • To determine the visual stimulation and instruction needed to help the person make use of remaining vision • To help the child to use this limited vision to the highest potential. • To plan programmes for specific curricular areas like orientation and mobility training or adaptive training in use of optical devices like magnifiers, telescopes etc. and non-optical a devices like reading stands, table lamp etc.

129 • To find which visual stimulation materials is most appropriate to the child • Determine nature of the primary reading medium-i.e., whether the child will need to be taught Braille or can he use large print. 4.4.3 Areas and skills covered in functional vision Visual skills used for functional vision follows the sequence of normal visual development. These visual skills are used to carry out every day activities. The assessment of functional vision has been based on the Low Vision Kit. The seven areas of skills to be assessed are: 1. Awareness and attention to objects Finding an object or target and looking at it (fixating) long enough to be aware of it or recognize it. Importance of assessment: Can a person see objects close to them? Does the person search for objects visually or with their hands? What makes objects easier or possible to be seen? Factors that affect how easy an object is to find or recognize are: • Size • Distance • Contrast • Familiarity (makes it easier to recognize) 2. Control of eye movements –Tracking Being able to follow moving objects with the eyes or hand movement Reason for assessment: can the person follow the movement of objects without “losing” where they have gone? Different direction of movements should be tested: • Up and down • Side to side • Diagonal and • Near to far 130 3. Control of eye movements- Scanning Accurately moving eyes and shifting his/ her from one object to another. Reason for assessment: Some people with low vision have to search around for a long time to find objects, and others may find it difficult to change from looking at near objects to look for something further away. 4. Discrimination of objects Recognizing objects from an outline or general shape. Reason for assessment: to learn if a person can discriminate between people and objects recognize familiar objects, recognize different or similar object. Objects can be discriminated because of their colours shape, contrast with the back ground, position or size, its distance the type of object, how familiar it is, and whether the objects is moving or still etc. Good scanning and discrimination skills is needed to discriminate an object. 5. Discrimination of details to identify actions and match objects The discrimination of details to identify an object is more difficult than seeing the object. Features of the object have to be identified. Reason for assessment: Most learning occurs from visual awareness and imitation. It is important to know what can be seen and how the environment (Such as lighting) affects what can be seen. The factors of distance, size, colour and contrast are very important. 6. Discrimination of details in picture Pictures can be simple outline or complex, detailed. The important features (parts) in pictures have to be identified so that the meaning of the picture can be understood. Reason for assessment: Pictures give useful information on posters , advertisement or in books, objects in pictures may be difficult to find and recognize 7. Identification and perception of patterns, numbers and words Matching letters and number by their similarity or their differences; this does not require reading but is a necessary skill for reading. Reason for assessment: to find out if a person can discriminate between similar and different shapes and letters. The result will help in making decision on whether a person should use normal size print, large print, low vision devices or needs Braille. *

Guidelines to develop better functional vision

131 • Recognize full sensory utilization and encourage it • Get visual attention to all tasks • The utilization of residual vision of low vision children should be stressed. • Makes the class room visually attractive • The school should maintain a case study containing Ø Eye report Ø Referral reports • Just having sight does not mean that we all use our eyes well. We have to train our brains to interpret what our eyes see. A person with low vision does not automatically try to make himself see unless he is extremely motivated to do so. He needs to be helped to interpret what he sees. He can develop good functional vision. • Visual functioning relates to how well a child is able to use his or her remaining vision for his or her everyday tasks. According to Barraga (1980), visual functioning is a learnt behaviour, primarily developmental, the more visual experiences the child has, the more the pathway to the brain is stimulated, which leads to a greater accumulation of a variety of visual images and memories. • It is the role of the special educators and parents to participate in the assessment of the low vision child. Assessment should address the implications of the child’s visual, social, emotional, and cognitive development. It is particularly important that functional vision assessment and observation should be done in the child’s everyday environment. • In the area of education, the resource teacher, itinerant teacher often function as a low vision instructor responsible for assessment. This allows for more communication between a regular teacher and the resource teacher which helps the low vision child to function well in the classroom. The modification needed should be based on the implication of the visual loss. The accessor’s cooperation and interaction, the school personnel and their understanding of low vision are the factors to be considered for effective learning. • The effectiveness with which a student is learning to use vision can be predictor of future success with aids. Some students compensate so well with visual skills that they may consider optical aids to be “too much trouble”. Some students hardly use their vision because they have encountered psychological difficulties or never have learned certain visual skills. They rely on other modalities from sighted helpers.

132 • The development of visual ability is not an inert overcome reflex but one aspect of the total behaviour of a person in the specific environment. Visual acuity is a misleading quality in estimating a person's seeing ability. Visual ability is not necessarily related to the kind of degree of impairment or loss of vision. It is a sequentially learned skill. • Even though the basic conditions of the eye remains unchanged, training and experience have been contributing factors in improving development of visual process, especially the degree of visual efficiency. The visual efficiency is essential to plan more precise programme for the use of how he/she is using vision and increases the students' efficiency. • There are a few research studies done on visual efficiency in relation to visual behaviour and the involvement of the resource teachers and special educators in developing the visual efficiency. • Implement the low vision stimulation programme for the integrated and the special school programme and improve the visual efficiency of the low vision children • Many of the programmes that have already started special training for the low vision have wound back due to the feeling expressed by their totally blind students that they are given less importance compared to the low vision students. Efforts have to be made to make the totally blind students understand that it is the need of the low vision students and not a factor of importance for them. • The low vision students have to be developed as a compliment to totally blind students. • Follow up result information related to the low vision child. 4.5

Tools for functional assessment of vision and skills: Functional Skills Inventory for the Blind (FSIB), Low Vision Assessment by Jill Keeffe, Lea Tests, and Portfolio Assessment. 4.5.1

Functional Skills Inventory for the Blind (FSIB) The success of an assessment depends on the object chosen. So use objects which are familiar to and interesting for the child being assessed. The size, distance, contrast, 133 colour, position and light on an around object are factors needed to be considered while testing. * The

Visual skills used for Testing Functional Vision 1. The Visual skills used for testing Whether the child has functional vision are listed here in

the order in which they should be assessed. The order of the skills follows the sequence of normal visual development. A child with low vision may be able to progress through all the steps without special training. Some skills may not be achieved but the child can still progress on to later steps. The areas of skills to be assessed are explained and examples are given of how the skills are used. These visual skills are used to carryout everyday activities. The methods of assessing the visual skills are described in the following section. 2. Awareness of Attention to objects The aim of this test is to find out the ability of the child to attend to an object. Choose a bright or shiny object like toys or balls about the size of your hand. Hold the object at the child's eye-level, standing one metre away from the child. Let the child look at the object. Ask him to reach for it and touch it. If the child doesn't show any response to the object (because he cannot see the object from a distance of one meter) the same procedure is followed by standing half a meter away from the child. If the object cannot be seen at less than half a meter, try to attract the child's attention with sound or movement. 3. Control of Eye Movements Tracking – Following a moving object. Activity: A bright ball can be rolled towards side of the child in a well lighted area. Stand beside the person and show him the object. Tell him to watch the object as you roll it and ask him to walk to it where it has stopped. You need to watch the child to see how far he was able to follow the object with his eyes. Note the distance he was able to track. Activities are provided to the child's

134 central and peripheral (Side) field of vision. When the child is able to track the ball, as next activity, a ball which is smaller in size or has less brightness can be used. When the child's performance is not appropriate, training is given to achieve the activity. Repeat the activity using shorter or longer distance depending on the result and record the distance till which the child was able to track the object.

4. Scanning – searching for a particular stimulus Among Other Visual Stimuli. Use two different objects about the size of your hand. Stand one metre from the child. Hold the objects in outstretched hands at your sides and front of the child at eye level. Name the object held in each hand. Let the child look at one object and then to the other object in turn. Show one object and then the other. Repeat this at least once. Example, look at the fruit, now look at the tumbler, back to fruit and to the tumbler. Activity Search for different shapes in the given shape card. There should be distinct horizontal eye and head movements from one object to the other. If the object cannot be seen from a distance of one metre move closer and record the distance at which the child could scan both the objects.

5. Visual Discrimination: It is the ability of the child to distinguish between near distant object. Choose objects which are familiar to child (coin, piece of food, spoon or plate).

135 The objects have to be recognized by looking at them without touching them. Record the distance needed to recognize near objects. Activity An activity for two dimensional items (Picture card) is given Discriminate the one which is deferent from the four figures given. Take the child to outside place where a variety of a activities are happening and where there are variety of objects. Note if the child recognizes objects, people and activities, record the distance for recognizing objects, people and activities.

6. Visual Figure-Ground Discrimination This refers to the ability of the child to isolate a particular picture/ object from the background, i.e. seeing the distinctive feature of an object. Ask the child to locate a particular spot on the picture. The child can be asked to identify buttons, belt, and shoes and also recognize actions in the picture. Activities Identify the stars which are similar to one in the smaller box

136 If the answers are not correct, ask the child to describe what he sees in the pictures. Record the answers and the distance of the eyes from the page.

7. Visual Memory This refers to the child's ability to store and recall past experiences and integrates those with new ones. Hide the objects the child has seen in the environment and ask him/ her to describe them. Present object/ pictures (like play activity e.g., Cricket or picture of zoo etc.) of an activity sequence on flash cards in a particular order and then remove them. Ask the child to recall the sequence in which the cards were presented. Give diagram of activity sequence on flash cards. Record the child's answer. Activity This type of informative picture can be given for a few minutes say one or two minute to observe. Get back the picture. Ask the child to describe what she has seen in the picture.

8. Visual Closure It is the ability of child to perceive a total picture or object when only a part is visible/ available. Ask the child to identify the missing part in an object/ figure. Note whether the child is able to do so or not. E.g. picture of animals, jug or a chair in part. Activity Provide a part of picture and ask the child to identify what they are: From Constancy It is the ability of a child to perceive the same object at different angles. Objects like comb, fruit can be held at different angles for identification. Picture of a tree, bucket, chair, spoon etc, can be pasted at different angles and the child should be asked to identify the object. Record the result.

137 Activity Pictures are examples of tree in different position. Ask the child to identify picture :

9. Eye-Hand Coordination It is the ability of a child to perform a task using hands and eyes in harmony. Ask the child to put a particular coloured bead in the thread provided. Ask the child to tear waste paper along the lines that you have marked Ask the child to colour a particular object in a picture Ask the child to throw the ball below the net Activity Ask the child to join the numbers in order and record the result

10. Eye- Foot Coordination It is the ability of a child to perform a task using eyes and foot in harmony. Choose an outdoor pathway. It could be a path from one building to another building or through the bush. The pathway should contrast with the ground on either side. Ask the child to walk in front of you. Follow closely to keep the child from coming to harm by falling or bumping. Observe if the child is aware of the sides of the path to follow. Check if he can see turns in the path and does not trip over rocks or hit over hanging branches.

138 Activity A circle with white chalk can be drawn on the floor like cited below and ask the child to step on the markings. The results give an understanding of the effects of the Low Vision for each child and how residual vision can be used. The results show the importance of factors such as distance, size, contrast and light for each child. The result should be discussed with the child with Low Vision, his family and other such as teachers and community based workers. It can be used to plan and execute a vision training programme. 4.5.2 : Low Vision Assessment by Jill Keeffe Simple but effective tests have been developed by Dr. Jill Keeffe for the WHO annual –Programme for the Prevention of Blindness. These tests of distance and near vision based on E - test have been field tested in 32 countries and found to be appropriate for developing countries and their effectiveness for screening for low vision has been confirmed. The tests are simple to learn to use. The result can be easily interpreted and the test materials are portable. This screening helps to detect people with impaired and those with potentially normal or low vision. Testing the Distance Visual Acuity. The first step is to test distance visual acuity. It does not matter if a person cannot read for this assessment using the E test card. The test distance is 6 metres (20 feet) for distance vision. The person must stand at 6 metres from the assessor. Six metre distance must be measured using measuring tape.

139 If measuring tape is not available, a six metre cloth tape preferably white in colour, marked at each metre can be used or the assessor may measure or count the number of his/her steps equal to six metre. The chart should be placed at a distance of 6 metres from the child. The E chart may be placed hanging against the wall or held at the hand. Whether it is hung or held at hands it should be at the eye level of the child / client being assessed. The child should be explained that the arms of the letter E are directed in different directions. For younger children an E cut out made of black cardboard can be given in their hands to show the directions. The visual acuity measurement can be started by testing the smallest symbol that can be (the directions) recognized. But due to limited visual ability it can be begun with the top line on the chart and proceed downward to the child's limit. Light should shine without glare on chart. Room illumination should be constant without light shining into child's eyes. Visual acuity is represented as a fraction. Acuities First Line 6/60 Second Line 6/36 Third Line 6/24 Fourth Line 6/18 Fifth Line 6/12 Sixth Line 6/9 Seventh Line 6/6 The numerator indicates the distance from the chart at which the test is conducted. The denominator means the smallest line of letters that the child can read from the testing distance. Procedure for Assessment • Test eye separately • Always begin with the right eye.

140 • Occlude or close one eye. In the case if right is being assessed, left eye is occluded. After testing each eye separately, test both eyes. If the child wears corrective lenses (spectacles) test child with lenses. Begin testing the visual acuity without spectacles and then test with the correcting lenses. The measurement of visual acuity while wearing spectacles should be considered. • The child should identify characters by pointing when using E chart. • Record the last line the child read and that is the visual acuity of the child. For example, if the child reads the third line and could not identify the characters in the next line (fourth), the child's visual acuity recorded as 6/24. If 3 responses out of 4 are correct no further testing of distance vision is needed. Record the visual acuity. In case where the child is unable to read the uppermost letter on the chart, he/she should walk one metre. After one metre forward, until the child can see the top line or symbol. The distance between child and chart becomes the numerator and vision is recorded as such 5/60, 4/ 60, 3/60. Test visual acuity with the large E at 2 or 1 metre. If the child does not recognize the top letter from a distance of less than one metre from test whether the child identifies finger counting or only hand movement or able to perceive only light or total absence of light. The child may have usable vision and it is important to discover the amount and quality of vision even though it is limited. If the vision is being tested, the World Health Organisation (WHO) categories should be used. • Normal vision is acuity of 6/18 or better • Low vision is acuity less than 6/18 • Blindness is acuity less than 3/60 For functional description low vision is considered vision up to light perception because the child with light perception can use the vision to identify doorways, discriminate day and night, for direction concept, mobility etc. For child with low vision, spectacles may improve the vision but not correct it to normal.

141 The Assessment Form : ANNEXURE- 1 Screening of Impaired Vision Name of the child : Standard : Cause of Visual Impairment : I. Visual Acuity (Distance Vision) Without correction With correction R.E _____
_____ L.E _____ Both Eyes _____ II. Near Vision N 48 N 20 N 8 III Visual Field Normal/ Restricted/Severely Restricted Date : Signature of the Assessor Testing near vision The purpose of testing near vision is to determine whether the child can perform near vision task like reading or what changes the child needs to perform the task or modification in the environment require or visual aids would be useful. The results of a near vision show the child's ability to see the details of near objects within the arm's distance from the body. Near tasks include eating, personal care and hygiene, leisure activities, sewing and reading. Near and distance vision is not always affected to the same degree in all eye conditions. In children near vision is often not as severely affected as distance vision.

142 The near vision test card has three sizes of Es. The smallest size of the Es is N8 which are similar to the print size of the adult or children in middle school level. The middle size Es are N20 which are similar to the print size books of children in standard –I. The largest size of Es is N48 which are similar to headings in books and newspaper. E E E E E E E E E E E E E E Testing procedure • No standard distance is required. • The test card is held at the distance preferred by the person. • The light should come from behind and to one side of the window. Make sure that the person is not looking towards the sun or other bright light. • Start with large Es. If the child cannot see these, tell him to hold the card closer to eyes. • Record the smallest the child is size the child is able to read correctly. For example if the child reads the smallest size of the letters in the card, record the near visual acuity as N8. 4.5.3 : LEA Vision Test System For Assessment and Screening The International Classification of Functioning, Disability, and Health (ICF 2001, ICF- CY2007) is the basis for assessing functioning and disabilities and requires consideration of all impairment and disabilities. The ICD- based measurement of visual acuity and visual field is adequate for reporting visual impairment in surveys, where visual acuities are reported for both distance and vision (WHO/PBL/03.91,http:// whqlibdoc.who.int/ hq/2003/WHO_PBL_03.91.pdf).

143 Visual acuity test is the test most frequently used to assess visual functioning. These tests are designed so that geometric progression is the same at all visual acuity levels and spacing is proportional, i.e. on each line it is equal to the width of the optotypes on the line. Only a limited number of tests have the required structure. They include test based on Sloan letters like the ETDRS test (Ferris et al 1982), on British letters (Bailey and Lovie1976, Salt et al 2007), and on LEA symbols and LEA Numbers (Vaidhyan et al 2007). These tests have been calibrated against the reference optotype, the Landlot Ring, and provide similar visual acuity values. The small differences found in visual acuity values in several studies depend on the structure of the cohorts. Some studies included extrafoveal measurements, which affect the values specifically for each set of optotypes. In an ideal test, the optotypes blur equally at threshold (LEA test). If differences exist with optotype recognition, optotypes are selected to include a certain number of easy and difficult optotype on each line (Sloan letters). Visual Acuity The LEA test require recognition optotype. This requirement differs from resolving the direction of lines in the E-test or the gap in the C-test. In the assessment of visual acuity the goal is to measure the ability to recognise pictures of common objects, as well as characters and numbers. Children's visual functions and communication during the assessment vary. Therefore, several tests have been designed to assess visual acuity in difficult test situations. Visual acuity test includes: - Test with single symbols for measurement at distance and near - Line test for measurement at distance and near - Test with tightly spaced optotypes - Test at low contrast 25%, 10%, 2.5% and 1.2% Near and distance test based on the same optotype reveal difference in visual acuity between distance and near vision and are, thus, an improvement compared with the present situation in many countries where near vision is measured with text tests only. LEA symbols visual acuity tests are single optotype test, standard line test, and line test with tightly grouped optotype. Single symbols test from near (40cm) and distance (3m) are the easiest optotype tests because there is no interference by surrounding visual information. LEA Numbers visual acuity tests are fewer in number than the symbols test because there are less often difficulties in communication in the assessment of school children and adults. The visual acuity line tests have 100% spacing between

144 optotypes. Near test includes spacing of 50%, 25% , and 12% to assess vision for reading and detect difficulties with other crowded information. To achieve accuracy in measuring visual acuity, the tester should not point to individual optotypes. Pointing gives a visual reference, which improves fixation and visual acuity. Pointing to individual optotypes is likely to reduce amblyopia detection. The tester can cover the line above the line to be read that the tester and the child are reading the same line. If a child's oculomotor functions are irregular, the screening test with more space between the lines in the near test and only one line visible on each page in the distance test facilitate testing. If fixation is stable but the saccades are irregular, the LEA puzzle can be used as the key card, which will allow child to feel the optotype forms without having to look at them. Many Young Children need a training period with the LEA Puzzle to learn matching or naming. While the child is playing with the LEA Puzzle, the test may observe the child's eye-hand coordination and visual and motor spatial memory by the turning the Puzzle board without the child noticing. The detailed instructions for testing are on the homepage www.lea-test.fi. Grating Acuity Grating acuity is measured either as detection acuity with LEA Grating in a preferential looking situation or as discrimination acuity using LEA Grating Acuity Test, which requires the ability to define and show or describe the orientation of the line. Contrast Sensitivity Contrast Sensitivity is measured with optotype and grating test. If the result from the measurements of contrast sensitivity, visual acuity value, and grating acuity value are marked on the recording form, the type of visual information transfer at different contrast level is clearly depicted. Colour Vision "Colour vision Testing Made Easy", created by Terrance Waggoner, OD, works well in testing young children's colour vision. Quantitative measurements are possible with the Panel 16 colour vision test. The test can be trained at www.lea-test.fi section Games. Motion Perception Detection and discrimination of slow movement can be tested with the pepi test, which can be copied from www.lea-test.fi. This test can be used to assess the vision of infants by observing the following movements. Older children can describe whether or what 145 they see. Johansson's " Walking Man" can be used to test perception of biological movements. Visual Adaptation Visual adaptation changes early in many retinal disorders. The functionally important cone adaptation can be observed during the CONE adaptation test game. This test requires a room where the illumination can be changed quickly from photopic to mesopic luminance to measure cone adaptation time. Direction and Length of Lines These two basic structures of pictures may be falsely encoded when entering the brain or distorted in the higher visual functions. This can be tested using the LEA Mailbox and LEA Rectangles. Heidi Expressions Children may have specific loss of perception of facial expressions. To discuss facial expressions with young children, the Heidi Expressions cards can be used as a matching game. If you have not used the test before, practice with normally sighted infants and children with age appropriate behaviour. When you feel comfortable holding the test and can concentrate on observing child's way of answering, you are ready to set children with disabilities.

4.5.4 Portfolio Assessment

Historically, the traditional school examinations consisted of a set of questions to be answered orally or in writing. In either case, the examinee composed and formulated the response. The term "essay question" come to be used broadly to cover all free- response question, including not only those demanding a lengthy essay but also those requiring the examinee to produce a short answer or to work out the solution for a mathematical problem. "Objective question," by contrast, were those that called for the choice of a correct answer out of the alternatives provided for each question. Although there are several kinds of items that require examinees to select a response, such as true-false and matching, the multiple-choice question has been, by far, the most widely used, the most thoroughly studied, and, also, the most frequently criticized type of test item.

146 Critics of the multiple-choice format argue that it promotes rote memorization and learning of isolated facts rather than development of problem-solving skills and conceptual understanding. In addition, many uniformed people within the educational and political establishments equate multiple-choice items with standardized testing and disparage both of these elements of assessment methodology at once. In an ironic turn of events, the same standardized testing programmes used to chart educational progress often have been seen as contributing to the educational deficits they have uncovered. Unfortunately, the criticism about excessive and inappropriate use of standardized test as been thoroughly justified in some cases. At any rate, charges that testing drives the curriculum and that both are in urgent need of reform have emanated from educators at all levels and have grown increasingly stronger in the past two decades. Advocates of educational reform believe that a major overhaul is needed in curricular goals and instructional method, as well as in the tools of assessment, and they perceive all of these areas as inextricably tied. Since the philosophical, political, and practical aspects of educational reform are beyond the scope of this book, we shall confine ourselves to discussing some of the proposed alternatives in assessment methodology. These alternatives are described by various rubrics, such as "performance-based" assessment, "authentic" assessment, and "direct" assessment. The method known portfolio assessment provides another set of alternatives. This type of evaluation tool is aimed primarily at making the process of educational assessment as meaningful and realistic as possible. Although there are a wide range of procedures to which the term is applied, a portfolio usually consists of a cumulative record- collected over an extended period of time- of samples of students' work in specific areas, such as writing or any other endeavour that involves a process in which progress can be documented. The portfolio method of assessment offers a great deal of flexibility and can be implemented more or less formally and with various degrees of collaboration between the student and the teacher. The reader will have gathered even from this brief overview that a great deal of attention is being paid to the means by which evaluation of learning and of students' work are conducted. This concern extends not only to what different items measure and how well they measure it, but also to other psychological aspects of test items. For example, Zeidner (1993) has investigated students' attitudes toward item formats and found that they prefer multiple-choice items rather than essays. Lu and Suen's (1995) research indicates that performance based assessment tends to favour field-independent over field dependent students. Other investigators have looked into the relationship between test anxiety and item type and found that scores on constructed response test seem to be more affected by anxiety than those of selected response tests. At the same time, the empirical literature concerning the strictly psychometric properties of performance based tasks used in academic settings has been accumulating gradually. Both the pace of the research and the direction of the result differ widely depending on the specific types of items in question. A fairly large number of students have investigated the reliability of the scoring procedures used for constructed response task.

4.6 Tools for psychological assessment of the Visually Impaired 4.6.1 : Vithova Pakinikar Performance Test It would be worthwhile, at the outset, to describe, in brief, the development of Intelligence Testing from Binet, the pioneer in this field to the present day problems in this field including the work done that is useful in measuring intelligence of the blind. Measuring intelligence by age Scales is the first stage. Binet's tests were first published in a graded form in 1905. They were again published in 1908 and 1911 in the form of an age scale ranging from year three to adulthood. D. Wechsler's Bellevue Intelligence Scale (1944) both verbal and performance has shown a good way to get over the difficulties referred to above. His method of converting total scores into I.Q.'s as standard scores is most useful from the practical point of view. The above scale is a point scale as distinguished from age scale. The method of finding I.Q. by this scale is easier than one of finding M.A. and then I.Q. Mr. K.K.Pakinikar has followed D. Wechsler's method of finding I.Q.'s. Apart from the above Wechsler Bellevue Intelligence Scale (WBIS), he has to his credit the following viz. Wechsler Adult Intelligence Scale (WAIS) and Wechsler Intelligence Scale for Children (WISC). All are widely used. Then comes the stage of performance Test for measuring intelligence. The pioneers in this field were Healy and Fernad (1911). Other prominent names in this field are: Fnox Pintner and Patersen, Gwyn kempf Schmitt, Hall Bruckner and King Gluk, Anderson, Kohs, Woodworth, Wells, Goddard and Alexander. At the beginning single tests were standardized. But to arrive at subject's I.Q.s a scale of scale performance Test was needed. The first of this kind is given by Pintner and Paterson (1917). Individual standardized Performance Tesst were included in the scale to form a battery of performance Test.

148 A significant point about performance test has not been referred to so far. Originally they were designed for measuring intelligence of the physically handicapped, or of those who had language difficulty. They were also used to supplement the finding arrived at by verbal tests. Whether they will be most suitable for measuring intelligence of the blind will be seen in the discussions that follow. Obviously, the blind can take verbal test using their auditory power. But then the tests are to be presented orally only. This necessity will certainly put limitations to the presentation of the test. The experiences usually better gained by sight, e.g. forms of objects are out of question in an oral test. Secondly, the oral test will be time consuming. There is another handicap for the blind in having a test with the help of a printed question. It cannot be in the usual script. It must be in Braille and if it is presented in Braille and the test cover all aspects of intelligence. The bulk of paper to be handled will be big and the taking of the test will be cumbersome and time consuming for the blind. Earlier the writer has referred to the inherent difficulties in standardizing a verbal test for the blind. Difficulties in administering it are also noted. Individual performance tests, though standardized, will not give true picture of the intellectual potential of the blind unless they form a battery of tests. Secondly, individual performance tests that are now used with the blind are given with suitable modifications in the original tests for the sighted. Comprehensive Performance Scales for the sighted have not as yet been tried on blind population. These Scales also are time consuming and in certain sub-test there is an element of trial and error. Hence the need of comparatively shorter battery of performance tests for the blind, which are nearly void of any chance element in them. The writer has genuinely tried to give to the blind population such a battery of Performance Tests. The writer has already referred to the experimental finding that visual impairment does not impair the intellectual potential. Human experience shows that there have been intellectual giants and mental defectives among the blind. The writer knows many blind geniuses. During the testing programme in blind Schools the writer came across mental defectives who were a great strain on teachers' capabilities for handling the handicapped during teaching periods. Predictive value of intelligence tests is unquestionable now. Problems of the blind have now passed from the social level to the educational. A shorter scale of performance Tests, therefore, is needed to spot out the genius and to weed out the M.D. from the population in schools.

149 Selection and description of performance tests for the blinds The tests that are included in the present performance Scale are based on the tactual and kinaesthetic experiences only of the subjects to be tested. Visual experiences though the richest –in-life, are out of question here. The other Performance Scales referred to test of memory, e.g. repetition of digits by tapping blocks in a particular order, number formation by means of dominoes and actual repetition of digits or consonants. The first two tests require visual experiences and the third auditory ones. The first two are out of question with the blind. The third type may be included in a performance Scale for the blind. During the testing programme, we used tests of repeating digits in the same order or the reverse according to the scheme at different age levels as given by Kamat in this revision of Binet's scale. This was continued till more than 150 subjects were tested. The experience was discouraging as in general, the blind subjects did not pass the test at their age levels. When inquired, otherwise intelligent subjects, remarked that they could not easily attend to the repetition of digits by the examiner. This finding goes against the general impression that auditory experiences of the blind are better than those of sighted persons. It would be worth while if we quotes significant observation of Dr. Kamat under 'repetition' tests in this scale. 1) It is difficult to secure attention to the repetition of digits by the examiner. 2) Trial series are, therefore, included in a repetition test. 3) Repetition test should not come first. It should be taken later after the examiner sees that the subject is taking tests easily. 4) Several repetitions of practice series may be required. 5) Three trials are given and the subject should pass at least in one trial. 6) Even with repetition of meaningful syllables a second repetition may be required. If the subject passes, do not count success but go to the next trial. 7) A repetition test puts strain on the mind. Hence it should not be given at the end of the examination. Fatigue is setting in them. 8) Even with the repetition of meaningful syllables the subject's attention may flag. So two trials with one error each may be taken as a success. 9) Practice may begin with a trial at a lower age level. 10) Memory for digits falls off after 16. The Paknikar has purposely quoted these observations to show that a 'Repetition of Digits' Test seems to be a handicap to a blind subject. Why should another handicap be added to the natural one or one brought by misfortune namely, loss of sight? He has dilated on this point as objection may be raised to his omitting 'repetition of digits test in the thus barring the subjects auditory experiences leaving only two types of experience, viz., tactual and kinaesthetic to be used. Secondly, the tests are included in the scale according to the criteria that are generally accepted. The criteria are statistical and other.

150 1. The nature of the scale, whether age or point, should be next consideration. The Paknikar has discarded the age scale as he thinks that deciding upon the median time for successful performance at each age level, for assigning age to each test is a very laborious process. He has also refer to the drawbacks of an age scale. It is easier to fix points to each test if highest time limit for complete performance at lower age level is considered. This has been strictly followed. Success with in time will earn some points. Success beyond time-limit will earn zero score. 2. The scale should not measure any specialized ability. The test materials is so simple that even manipulative skill is out of question. 3. Maximum scores should not be obtained by most subjects. There has been gradual rise in average score from the lower age level to the higher age level. 4. The tests should discriminate well at all levels of intelligence from the lower to the higher. The results show that subjects at higher ages take less and less time to complete a test as compared to subjects at lower ages. 5. There should be no cases where subjects of higher age fail while subjects of lower age pass. No such cases are found with the exception of M.D's. 6. On actual try out it was found that tests 1 to 5 worked well. There was a short pilot study. At the first stage, these tests were tried by three sighted adults blindfolded to see how they would work with the blind. They had the impression that latter tests would not work well. Then they were tried by a blind pupil from a secondary school. Surprisingly, they worked well with the blind subject. She was successful in even those tests in which the adults failed trying them blind-folded. Later some sighted children also tried these tests blind-folded with interest. These cases are not included in the sample on which norms are based. The usual method of a pilot study could not be adopted as the subject in pilot study cannot be included in the actual data. In the case of blind population this would entail a loss in actual data which is available with great difficulty. Hence the objective in this pilot study was to see how the tests of circle formation would work with the blind. 7. Experience with the test should determine the validity of the scale. Generally correlation with recognize tests and teachers' rating are considered. 8. The test should lend themselves to scoring with relative ease. 9. An average individual with average opportunity should be able to acquit of himself well. It is so with the tests.

151 10. There should be increasing frequency of success in test with higher intellectual level. It is so found. 11. There should be some order of difficulty in the test. When the nature of test is similar they are arranged according to difficulty- from simple to complex. 12. The test should be interesting to the subject. Mr. Paknikar experience with the blind subjects tested was that their interest did not flag during testing time. 4.6.2

A short scale I.Q. measure for the Visually Impaired based on WISC-R

The intelligence scales developed by David Wechsler include several successive editions of three scales, one designed for adults, one for school age children, and one for preschool children. Besides their use as measures of general intelligence, the Wechsler scales have been investigated as a possible aid in psychiatric diagnosis. Beginning with the observation that brain damage, psychotic deterioration and emotional difficulties may affect some intellectual function more than others, Wechsler and other clinical psychologists argued that an analysis of the individual's relative performance on different subtests should reveal specific psychiatric disorders. Antecedents and Evolution of the Wechsler Intelligence Scales. : The first form of the Wechsler scales, known as the Wechsler –Bellevue Intelligence Scale, was published in 1939. One of the primary objectives in its preparation was to provide an intelligence test suitable for adults. In first presenting this scale, Wechsler (1939) pointed out that previously available intelligence test had been designed primarily for schoolchildren and had been adapted for adult use by adding more difficult items of the same kinds. The content of such tests was often of little interest to adults. Unless the test items have a certain minimum of face validity, rapport cannot be properly established with adult test takers. Many intelligence test items, written with special reference to the daily activities of the schoolchild, clearly lack face validity for most adults. It was in order to meet these various objections that the original Wechsler Bellevue was developed. In form and content, this scale set a basic pattern for all the subsequent Wechsler intelligence scale, each of which has, in turn, added some refinements to its immediate predecessor. In 1949, the Wechsler intelligence Scale for Children (WISC) was prepared as a downward extension of the Wechsler Bellevue (Seashore, Wesman, & Doppelt, 1950). Many items were taken directly from the adult test, and easier items of the same type were added to each subject. The Wechsler Bellevue itself was supplanted in 1955 by the Wechsler Adult intelligence Scale (WAIS), which corrected some of the

152 earlier scale's technical deficiencies with regards to size and representativeness of the normative sample and reliability of the subtests. The development of the WISC was somewhat paradoxical, since Wechsler embarked upon his original enterprise partly because of the need for an adult scale that would not be a more upward extension of available children's scales. The first edition of the WISC was, in fact, criticized because its content was not sufficiently child-oriented. In the revised edition (WISC-R), published in 1974 and designed for 6 to 16 years-olds, special efforts were made to replace or modify adult oriented items so as to bring their content closer to common childhood experiences. In the Arithmetic subtest, for instance, "cigars" was changed to "candy bars". Other changes included the elimination of items that might be differentially familiar to particular groups of children, and the inclusion of more female and Black persons in the pictorial content of the subjects. Several of the subtests were lengthened in order to increase reliability. Improvements were also introduced in administration and scoring procedures. Description of the Scale: By now, each of the three Wechsler scales has gone through one or more revisions. The current versions, published under the name of David Wechsler even after his death in 1981, are the Wechsler Adult Intelligence Scale- Revised (WAIS- R-Wechsler, -1981), which covers the age span of 16 to 74 years; the Wechsler Intelligence Scale for Children- Third Edition (WISC-III-Wechsler, 1991), intended for children aged 6 years to 16 years and 11 month; and the Wechsler preschool and primary scale of intelligence revised (WPPSI-R-wechsler, 1989), which now covers the range of 3 yers to 7 years and 3 months. WAIS- III has been revised in 2005 and named WAIS- IV. WAIS- III has some advantages. Its major advantages are as under: i) It incorporates the modern multidimensional nature of human intelligence, including fluid intelligence and processing speed. ii) It incorporates the possibility of pattern analysis. iii) It is appropriate most suitable for assessing adult human intelligence. iv) It uses deviation IQ. v) It has impressive degree of reliability and validity. vi) It uses a point scale. 153 vii) It makes provision for index score which provides a support to multidimensional nature of human intelligence. However, WAIS – III has also some disadvantages as under: i) It is a poor measure of extreme levels, that is, high or low level of intelligence. ii) It does not take into consideration the theories of multiple intelligence as enunciated by Gardner(1983). iii) It has poor reliability for the individual subtests. The WAIS-R, WISC-III, and WPPSI-R share many features, including their basic organization into Verbal and performance scales each of which consists of a minimum of five subtests (and a maximum of seven) and yields separate deviation IQs. The individual scores on all 10 of the regularly administered subtests (11 for the WAIS-R) are combined into a Full Scale IQ which has a mean of 100 and an SD of 15, as do the Verbal and Performance IQs. Of the 17 different kind of students used in the WAIS-R, the WISC-R, the WISC-III, and the WPPSI-R, eight(5 verbal and 3 performance subtests)are common to all three scales. In administering the scale, the verbal and performance subtests are alternated and given in a predetermined sequence that varies with each scale. The information subtest is the first verbal subtest to be administered in all three scales and serves as a good rapport builder. Efforts have been made to avoid specialized knowledge. The first items are easy enough to be passed by the vast majority of examinees, unless they are mentally retarded or have reality orientation problems. In such cases the examiner may quickly decide to discontinue the testing. The question in the WAIS-R and WISC-III version of Information cover facts that most person in the United States would have had a chance to learn, such as "What month comes right before December". The WPPSI-R has similar questions, albeit at a lower difficult level. The Arithmetic subtest is another verbal measure that illustrates the wide range of difficulty across the Wechsler scale. The easiest WPPSI-R Arithmetic items require pointing to the one object pictured in an array that illustrates a quantitative concept (such as "smallest" or more) The performance subtest of the Wechsler scale typically require the manipulation of

154 various objects. Such as puzzles and blocks, or the visual scanning of printed materials, like pictures or symbols. They all place time limits on the test taker, who in most cases is also given bonus points for speed. In the verbal scale, by contrast, only one subtest (Arithmetic) is speeded. Picture Completion is a performance subtest shared by all three Wechsler scales; it requires the examinee to identify what important part is missing from pictures of common objects or scenes. The items for the earlier ages rely on basic visual inspection—for example, by presenting the picture of an animal with a limb missing. Concluding Remarks on the Wechsler Scales The successive edition of the three Wechsler scales an increasing level of sophistication and experience in test construction, corresponding to the decades when they were developed. In comparison with order individually administered tests, their principal strengths stem from the size and representativeness of the standardization samples, particularly for adult and preschool populations, and technical qualities of their test construction procedures. The treatment of reliability and validity in the WISC-III manual is especially commendable. The popularity of the Wechsler scales assures them of a constantly expanding research base for the time being. However, some critics have noted that even the latest, most improved versions of the Wechsler scales may soon become obsolete in light of the current demands for links between assessment instruments and intervention strategies. In this regard, the weakest feature of all the Wechsler scales has been their lack of theoretical grounding, which makes it hard to find a coherent basis for interpretation. Furthermore, the composition of the scales seems to presume that the ability domains tapped by their subjects across age levels are the same because of the superficial similarities among test materials and tasks.

4.6.3 Adapted EPQ (Eysenck Personality Questionnaire)

Based on a lifelong programme of factor analytic questionnaire, Eysenck and Eysenck (1975) developed a series of test designed to measure normal and abnormal dimensions of personality. Eysenck identified three major dimensions of personality: psychoticism (P), Extraversion (E), and Neuroticism (N). The Eysenck Personality Questionnaire (EPQ) comprises items that intend to measure these three dimensions of personality. The EPQ consists of 90 statements to be answered in terms of either Yes or No and is specially suited for persons aged 16 and old. It also incorporates a Lie (L) scale to assess the validity of the testee, or examinee's responses. Also a junior EPQ is available for assessing these dimensions among children aged 7 to 15 and it consists of 81 statements. A brief description of these three scales are as under:

1. P Scale: P scale assesses the dimension of psychoticism which is not equivalent to psychosis such as schizophrenia although a schizophrenic is expected to score high on P scale. It assesses traits like poor concentration, poor memory, insensitivity, liking for unusual things, disregard for danger and convention, cruelty, lack of caring for others. Such persons are considered peculiar by others. A high score on P scale indicates impulsivity, aggressive and hostile traits, empathy defect and a preference for liking odd or unusual things. Antisocial personality and schizoid personality often obtain high scores on this dimension. A low score on P scale indicates some derivable characteristics like empathy and interpersonal sensitivity. A few examples of items of P scale are: Do you take risk just for fun? (T) Do you often break the rules? (T)
2. E Scale: E scale assesses the dimension of extraversion and its polar opposite introversion. High scores on E scale indicates tendency to be outgoing, preference for activities involving contact with other people, desire for novelty. Such persons are fun-loving and gregarious. Low scores on this scale indicate introverted traits such as preference for solitude and quiet activities. Such persons show tender mindedness, introspectiveness and seriousness. A few examples of items of E scale are: Do you like plenty of excitement? (T) Are you quiet when with other? (T)
3. N Scale: N scale assesses the dimension of neuroticism that includes traits like slowness in thoughts and actions, suggestibility, tendency to repress unpleasant fact. Lack of sociability, below average emotional control, will power and capacity to exert self. A high score indicates that the person is nervous, maladjusted and over emotional and a low score indicates that the person is stable and confident. A few examples of items N scale are: Are your feelings easily hurt? (T) Do you feel dullness in life? (T)

156 A major focus of research with the EPQ has been to find out the empirical correlates of extraversion and its opposite introversion and such researches have linked several perceptual and physiological factors to the dimension E-I. Some of the important such linkages are: (I) Extroverts have a greater need for entertaining external stimulation. (II) Extroverts are readily conditioned to stimuli associated with sexual arousal. (III) Extroverts are more suggestible than introverts. (IV) Introverts are vigilant in watch keeping. (V) Introverts' performance on signal detection tasks are comparatively more improved (VI) Introverts are less tolerant of pain but more tolerant of sensory deprivation. The psychometric properties of the EPQ are satisfactory. The one-month test-retest reliabilities were .78(P), .89 (E), .96 (N), and .84 (L). The internal consistency reliabilities were in the .70s. for P and the .80s. for the remaining three scales. The construct validity of EPQ is also well established in several studies using emotional, behavioural, attentional, learning and therapeutic criteria (Eysenck & Eysenck, 1975,1985).

4.6.4 Adapted Blind Learning Aptitude Test

Testing the blind presents a very different set of problems from those encountered with the deaf. Oral tests can be most readily adapted for blind persons, while performance tests are least likely to be applicable. In addition to the usual oral presentation by the examiner, other suitable testing techniques have been utilized, such as tape recordings. Some tests, such as the College Board Scholastic Assessment Test (SAT), are also available in large-type formats or in Braille. The latter technique is somewhat limited in its applicability, however, because of: the greater bulkiness of materials printed in Braille compared to those provided in ink; the slower reading rate for Braille; and the number of blind persons who are not facile Braille readers. The test taker's responses may likewise be recorded in Braille or on a keyboard. Specially prepared embossed answer sheets or cards are also available for use with true-false, multiple-choice, other selected response items. In many individually administered Tests, of course Oral or gestural responses can be obtained.

157 Among the earliest examples of general intelligence test that have been adapted for the blind persons is the Binet. The first Hayes-Binet revision of testing the blind was based on the 1916 Stanford-Binet. The most recent adaptation comparable to the Stanford-Binet from L-M is the Perkins -Binet test of intelligence for the blind. The Wechsler Scales have also been adapted for the blind test takers. These adaptations consist essentially in using the verbal tests and omitting the performance tests. A few items inappropriate for the blind are replaced by alternates. In general, the studies of children who have poor vision or blindness suggested that these conditions may have a negative impact on their cognitive development, even the verbal area, because of the limitations such condition impose on the range and variety of their experiences. Very few instruments have been developed specifically for use with visually impaired persons. Possibly the best known example of these is the Blind Learning Aptitude Test. (BLAT). The BLAT is an individually administered test that incorporates items adapted for other tests such as Raven's progressive Matrices, and other nonverbal items, and presents them in an embossed format. Emphasis is placed on the learning process rather than on products of past learning, which might handicap the blind child. Information regarding reliability and validity is scant and requires further research. Nevertheless, the BLAT can be useful component along with verbal tests, in the evaluation of blind children elementary school age. The Intelligence Test for visually impaired children incorporates haptic or tactile versions of tasks such as Block Design into a Battery that includes several on verbal and verbal subtests. As in this case all the other special conditions discussed, visually Impaired occurs in a wide ranges of gradations and quite often combination with other problems. Thus, the decision of whether to use standard tests, adaptations of them, or specially designed tests for the blind depends on the objectives of the assessment and the unique characteristics of the persons in question. In general, tests users should always remember that modifications tests such as tactile presentations of Visual design or extended time limits, cannot be assume the same constructs as the Original Versions.

4.6.5 Concept Development for blind children

Concepts grow out of the perceptual process and become enriched as the child develops language. The breadth of concept development is dependent in large measure on the breadth of the perceptual experiences. Because the blind child lacks one source of

158 sensory input, his perceptual processes are deficient. He may never grasp some concepts and need more experience than the sighted child to grasp other. A concept is a network of significant inferences by which one goes beyond a set of observed criteria properties exhibited by an object or event to the class identity of the object or event in question, and thence to additional inferences about other unobserved properties..... the network of inferences that are may be set into place by an act of categorization. The developmental theory of Piaget will from the frame reference for identifying mental developmental needs. Piaget's stages of intellectual development are outlined very briefly here. (For more details, see Flavell, 1963; Ginsburg & Opper, 1969; and Maier, 1665) The first 2 years of life are described as the sensorimotor stage. The infant progresses from purely reflex activity to more systematic and organized behaviour. He learns that he has some control over object world and will search for a toy he has lost. He learns that objects are independent for himself. Finally he learns to imitate and to respond to people through imitative behaviour. At approximately 2 years of age the child enters the symbolic pre-conceptual phase. The imitative behaviour of the previous period becomes internal imitation (accommodation) and provides the child with symbols which acquire meaning through assimilation. He will apply his symbols in a playful make-believe fashion to other situations as he tests out their appropriateness. He begins to use language for objects and events that may not be present at the moment. The child enters the phase of intuitive thought at about 4 years of age. This phase and the preceding pre -conceptual phase are sometimes called the preoperational stage. Language now becomes repetition, monologue and collective monologue; it is described by Piaget as egocentric, that is, the child is neither concerned with nor interested in what another is saying. By contrast, communication is based on interaction with others and has as a purpose the relaying or sharing of information. During this period, the child employs imitation more or less consciously in a pre-identification fashion. Further, he broadens his social horizons and interest in the world about him. From approximately 7 to 11 years of age the child passes through the stage of concrete operations. During these years, the child acquires the ability to order and to relate his experiences into a gestalt, or organized whole. He establishes system of classifications and moves from inductive to deductive thinking. While language is now a tool of

159 communication, he still employs symbolic speech without true understanding of meanings. He looks beyond his family for models to imitate. At about the age of 12, the child enters the stage of formal operations, the final period of intellectual development. During this stage, the adolescent moves from the concrete to the abstract. He enters the world of ideas. He formulates hypotheses concerning the various results of an action and considers what might occur. He utilizes language as a means of communicating thoughts and ideas. He reaches an understanding of his world and where he fits in that world. It should be remembered that the ages attached to the stages in this outline are approximate, and that development through the stages may not proceed evenly on all fronts. In case of blind children abstractions such as a concept of colour may never be formed, since the child has no possibility of acquiring a background of sensory input for this concept. His understanding of this group of concepts will of necessity remain on the verbal level and be based on what others have described to him. Thus, his grasp of such concepts will come only through various experiences and cannot truly be his own. In this area, he may have difficult moving beyond the stage of concrete operations. The concepts of distance and time illustrate another group which eventually may or may not be grasped, depending on the variety and number of experiences designed to give them meaning. For example, the sighted child may acquire some meaningful concept of distance by visual input, that is, how far he can see, and later through an understanding of relative as shown on a map drawn to scale. While the blind may reach some understanding of distance through his kinesthetic sense, he encounters difficulty in doing so. Walking a specific distance would be the most meaningful procedure, but a walk of sufficient length to give an idea of great distance would not be feasible. Further, his deficiency in grasping what distance is prevents his making maximum use of maps through his tactile sense in order to acquire a concept of relative distance. He needs many concrete experiences through his kinesthetic sense in order to use maps effectively. Educators need to be aware of potential difficulties of the visually impaired children in the area of concept formation and particularly should emphasize meaningful concrete experiences in order to maximize concepts that have relevance for the child.

4.6.6 Reading Preference Test for Children with Low Vision A research on "Development of Low-Cost Functional Assessment Kit and studying the Relationship Between Visual Acuity and Visual Efficiency of Low Vision Children " was conducted by the Dr. M.N.G. Mani from 1994-1997. This research work was

160 supported by the Educational Research Innovations committee of the National Council of Educational Research and Training, New Delhi. The study was conducted with 321 low vision children in the state of Tamil Nadu, India. It reveals that majority of low vision children do not have formal visual efficiency training. Moreover, there is empirical evidence that the higher visual acuity of the child does not mean that the visual efficiency too is better. The research reveals that visual efficiency skills of low vision children improve only through systematic visual efficiency training. Large print materials should be prescribed for some low vision children and not for all. While deciding about print reading, certain components such as prior familiarity of print letters, print size required, distance at which reading task is performed, fatigue, etc., have to be considered. Research reveals that a low vision student may use his vision for reading large print for a brief time may not be able to use it for a prolonged time. Similarly another student may use 30 points print size comfortably but all books cannot be presented such a magnified manner. Even use of magnifiers may reduce the field of vision. Still in some other cases, the vision in the low vision students may be deteriorating. Therefore all low vision students may not be benefited by large print materials or magnifiers. They require Braille for reading purposes while the residual vision can be used for mobility, reading news headline, etc. Therefore it is most essential to know the reading preference of a low vision child before prescribing large print or Braille. The Reading Preference Test (REPT) has emerged out of a thorough research and helps any practitioner to determine the print or Braille reading preference of a low vision child. The areas, which are considered as vital, in the assessment of the reading preference of a low vision child are: 1. Light perception: sunlight/Dim light difference 2. Light perception: Good light/ poor light difference in a class. 3. Light tracking 4. Detecting hand movement 5. Distance of detecting hand movement 6. Finger counting : Fingers raised one at a time 7. Finger counting: Fingers spread apart 8. Finger counting- (general): Fingers closed together 161 9. Finger counting inside the classroom with good lighting condition 10. Finger counting inside the classroom with poor lighting condition 11. Visual background 12. Colour detection 13. Visual Closure 14. Form constancy 15. Eye/hand coordination 16. Eye/ foot coordination 17. Print size preference without magnifiers 18. Print size preference with magnifiers 19. Time taken to read a passage (Mother tongue/ English) 20. Skill in reading both print and Braille 21. Ability to write 22. Writing speed. The REPT is not accompanied by a TESTING KIT. A testing kit was deliberately avoided to improve the usage of the test even in rural areas. Through some concepts like 'lighting condition' can be tested better under controlled and laboratory conditions, the test does not envisage children being tested so. The description of 'good' and 'bad' lighting condition is viewed in the context of the available lighting condition in the school or locality where the child with low vision is identified. Whatever condition perceived by majority of seeing children as 'bad' and 'good' lighting condition should be used with low vision children too. A contrived situation for testing not created. We are fully aware of the fact that such testing may not be accurate. However, it would be definite be indicators about the reading preferences of the vast majority of low vision children. Experiments with the most of the low vision children reveal that the environmental conditions created in REPT are appropriate. However, the reading preference of 2-3% of low vision children may not be detected by REPT. As the objective of REPT is to make reading preference assessment a mass movement for all low vision children in the rural areas, the expected benefits for low vision children far outweigh the forced limitation of the Test. Therefore, the limitation of the test is not by its construct by its concept.

162 The assessment items and the accompanying self- instructional guidelines are enumerated as follows: 1. Can the child distinguish between the light Perception in sunlight and the same under Cloudy Conditions? How to Test? If the child has light perception, he should Detect It when the sun comes out of the cloud. Therefore, the testing Should be done in such a natural condition. If the child succeeds, proceed to item 2. If no, the assessee is a child without light perception he is certainly a Braille reader. 2. Can the child localise the light source? How to test? For testing this, move a Torchlight in front of the child and see Whether or not he/ she is able to track The light source. If the child succeeds, he/she can involved in various educational experiments in science which involve light (for example, light rays pass in a line) but Still the child may be a braille reader. In Such a condition more difficult conditions may be tested. If no, light perception of the Child has only a very limited use in education. 3. Can the child detect hand movement in front? How to Test? For testing this, move your hand from left to right and vice versa in front of the child If yes processed to item 4. If no, the child will certainly be a Braille reader, but the residual vision is useful for mobility and other purposes. Yes: No: Remarks: Yes: No: Remarks: Yes: No: Remarks:

163 4. Can the child count fingers when they are Kept together? How to test? Show the palm with fingers with put together and ask the child to count fingers. If the child succeeds, see whether the child can perform the task under different lighting condition. If no, the child cannot succeed in print reading. Teach Braille but orient the child to scrip letters too. He can read large print with difficulty. 4.6.7 Cornell Medical Index for Visually Handicapped Children The Cornell Medical Index (CMI) was created in 1949 and its purpose as stated in the original manuals was:

100% MATCHING BLOCK 97/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

to meet the need for an instrument suitable for collecting a large body of pertinent medical and psychiatric data at a minimal expenditure of the physician's time. It serves as a standardized medical history and as a guide to subsequent interview: The original CMI was validated through several studies on populations of varying sizes.(

See: Lowe, DJ. The Cornell indices: A bibliography of Health questionnaires. 1975 : The Cornell University Medical College Library, New York, NY.([PDF copy available]) form

86% MATCHING BLOCK 98/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

Its inception through the 1970s, the CMI was widely used both at new York Hospital(

Now New York-Presbyterian

85% MATCHING BLOCK 99/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

Hospital) and throughout the country. It was considered valid, reliable, and reputable particularly since it bore the name of Cornell. The CMI had been copyrighted by Cornell University Medical College (now

the Joan and Sanford I. Weill Medical of Cornell University) so individuals wishing to use the CMI

93% MATCHING BLOCK 100/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

purchased the questionnaire forms and the manual from the medical college. By 1980 the situation had changed. The questionnaire was becoming out of date, particularly

in the language that was

100% MATCHING BLOCK 101/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

used. The supply of questionnaires was depleted and a reprinting was required. There was a concern about reprinting the CMI without some revision so the questionnaire was revised but only at the level of the wording. No substantive revision was made in the nature of the data collected by the questionnaire. The revised questionnaire was completed and

copy righted in 1986 and a new printing was completed. This revised version was sold until 1990. Cornell Yes: No: Remarks:

164 Medical Index is a medical subject Heading and this linked Pub Med/ Medline search will bring up a bibliography of the Index's use.

94% MATCHING BLOCK 102/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

Also in 1986, the issue of the future of the CMI was raised. Sales were declining and the college wanted to investigate the options available for marketing the CMI. Since it bore Cornell's name, there was concern with the product. A committee to study the CMI

Was formed

97% MATCHING BLOCK 103/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

with members appointed by the Chairs of Medicine, Neurology, and Psychiatry. The committee examined the issues concerning The CMI, did a survey of post customers, investigated other instruments available for similar uses, and looked at the content of the CMI. These investigations found that there were many uses of the CMI.

98% MATCHING BLOCK 104/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

These investigations found there were many uses of the CMI but the predominant use was by private practice physicians. Many of the comments the committee received indicated a need for revision although there were users who

are

95% MATCHING BLOCK 105/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

satisfied with it as is. The committee also found the CMI was no longer being used in the New York Hospital because it was not felt to be particularly useful. There also did not appear to be any enthusiasm by the individuals on the committee for revising and revalidating the questionnaire, something that would

need to

92% MATCHING BLOCK 106/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

be done if it were to continue to be actively marketed. As a result of this review, the committee concluded that the CMI was no longer a viable product and should be phased out. They believed that the CMI was a product that no longer served a useful purpose and that its continuance had been related more to its historical position than to its contribution to health screening. As a result of this review, the CMI was phased out over period, July 1990 - June 1991. Since that time, requesters were told that the CMI was out-of- print. The college still retains the copyright, however, so it could reinitiate the CMI in the future if there were clinicians interested in doing a revision and revalidation. Since 1991, requesters

have been informed that they could receive a sample copy and could

86% MATCHING BLOCK 107/112 SA SEVI-31 with glossary for alignment.docx (D127037367)

reproduce it for their own non - commercial use that they must take Cornell's name

of

78%

MATCHING BLOCK 108/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

the forms. This approach has allowed the College to respond to requests but at the same time inform the requester of the problems associated with using the CMI.

As of July 2001, this practice has ceased and now the CMI is available only for historical purposes and for research not involving human subjects. Individuals interested in receiving a copy of the CMI for these purposes should contract the Medical Centre Archives of New York- Presbyterian/ weill Cornell at (212) 746- 6072 or at email- archives@med.comell.edu.

165 4.7 Report Writing We will examine some of the broad issues involved in the communication of test results with particular reference to ethical and social implications. For the clinician, such communication usually includes the preparation of a written test report or case report that is often followed by discussion or consultation with the client parents, teachers, or other professionals. Even in those situations that do not require a written report, it is a good idea to prepare one as a record for future reference. The preparation of a report also helps to organize and clarify the clinician's own thinking about the case and to sharpen her or his interpretations. Report writing represents the final stage in the clinician's synthesizing function. In its content, the report should draw upon all the data sources (test and non test) available to the clinician. Several books provide guidelines for report writing. Without duplicating the many lists of suggestions that can be found in such sources. We shall focus on some of the major points. First, there is no one standard form or outline for all reports. Both content and style should and do vary with the purpose of the assessment, the context in which it is conducted, the persons to whom the report is addressed, and the theoretical orientation and professional background of the clinician. It is especially important to adapt the report to the needs, interest, and background of those who will receive it. For example, a report addressed to a lawyer needs to be quite different from one address to a psychotherapist. Nevertheless for both of them, the clinician should select what is relevant to answering the questions raised at the outset from the mass of data he or she has gathered. The report also should concentrate on each individual's differentiating characteristic – the high and low points- rather than on traits in which the individual's standing is close to the average. A test of the effectiveness of a report is to see whether it is unique to the individual or whether it applies equally well to other persons. It is a relatively easy task to prepare a pseudo-report from general, stereotyped statements that apply to most people. A considerable body of research has demonstrated that such reports are readily accepted as "remarkably accurate" self descriptions by a large majority of persons (Goodyear, 1990; Klopfer, 1983; Snyder & Larson, 1972; Tallent, 1992, pp. 236- 238). This pseudo validation has been called the " Barnum effect", after phineas T. Barnum, the famous showman who is credited with the remark that there's a sucker born every minute. Reliance on such generally applicable personality descriptions is a favourite device of fortune tellers and other charlatans. The primary focus of the report should be on interpretations and conclusions, although

166 test records and other detailed data may be separately appended in some cases. Specific data, such as individual responses and subject scores, should ordinarily be cited only to illustrate or clarify a point. Reports should be carefully organized and integrated. Books on the preparation of assessment reports usually contain helpful hints for good writing as well as references to standard manuals of style. One particularly entertaining little book that should make writing less painful for both writer and reader is the Elements of Style by Strunk and White (1979) 4.8 Check your progress 1) Write down the importance of early identification and intervention programme for children with low vision.

168 4.9 Let us sum up

- Ø Early intervention services have significant impact on the visually impaired infants and toddlers. Early intervention plays a significant role in preventing and reducing the extent of developmental delays. It is important to identify children who have impaired vision. The children with visual problem can be identified within some eye conditions. Vision may be improved with spectacles, treatment or operation.
- Ø A clinical low vision evaluation assesses whether or not a child will benefit from optical devices such as monocular telescopes and or magnifiers. An optometrist or ophthalmologist who specializes in low vision and the prescription of optical devices performs the clinical low vision evaluation.
- Ø Simple but effective tests have been developed for vision screening.
- Ø Functional vision is the used of vision for particular activities. Functional visual skills are required to carry out every day activities.
- Ø This assessment provides information regarding a student’s ability to use his vision within the learning environment. It includes acuity, colour, fields, and environmental accommodations.
- Ø A child with low vision may be able to progress through sequential training of visual skills.
- Ø Children who have very little vision or have not used vision need to know that they can use their vision. They may also need encouragement to do so.
- Ø Visual efficiency is the processing ability of the brain. It is unique to each child.
- Ø At this efficiency level those with low vision learn to distinguish patterns of visual stimuli, differentiate outlines, inner detail of objects and transfer this learning into two dimensional pictures and symbols.
- Ø The visual efficiency can be developed by training but cannot be measured clinically.
- Ø The visual skills to be trained are visual attention and awareness, control of eye movements, scanning. Tracking visual discriminations, visual figure-ground discrimination, visual closure, visual memory, recognition of action, form constancy, eye hand and eye foot coordination. Normally students with low vision may have additional visual fluctuations,

169 such floaters in the visual field, light sensitive, eye fatigue, degenerative condition etc. Parents and teachers must continue to provide creative and meaningful visual stimulation in order to foster the presentence. It is essential that the student understanding his or her functional vision and the best techniques for sight utilization. Assessment of the student’s functional vision in the initial step in teaching or rehabilitating student how, when and under what conditions vision can be used efficiently. Assessment will provide all physical data on the eye report obtained from the eye care specialist. Secondly the information collected should be presented to each student in a vocabulary appropriated for him or her level of understanding. From this data information in the area of low vision is formulated for the student. Teachers and parents can never know what children see, only how they function. Collecting functional data over a period of years serves two important purpose. It helps students reach maturity with objective knowledge about their visual abilities and disabilities. in addition it provides a continuous record of change in their visual status.

Assessment of Learning Needs of Children with VIMD Structure : 5.1 Introduction 5.2 Objectives 5.3 Concept and definition of VIMD 5.4 Etiology of VIMD 5.5 Impact of VIMD on learning and Development 5.6 Screening, Identification and Assessment of Visually Impaired Children with Associated Disabilities 5.7 Multi-disciplinary assessment of visually impaired children with Associated Disabilities 5.8 Check Your Progress 5.9 Let Us Sum Up 5.10

References 5.1 Introduction When a child has several different disabilities, he/ she has multiple disabilities. The group of multiply disabled visually impaired children is a heterogeneous group. The effect of multiple disabilities can be more than the combination of two individual disabilities. The problem is that these children do not seem to suit the schools where they are placed. Because children with multiple disabilities have problems with all muscle movement, with understanding and often with seeing and hearing as well, communication is very difficult for them. The status of education of visually impaired with multiple disabilities is in the low priority. Intervention at earliest possible stages will definitely improve their developmental skills, optimize abilities and build a foundation for future learning.

171 5.2 Objectives After going through this unit the learners will be able to : ❖ Define the concept of multiple disability . ❖ State the current status of education of children with multiple disability . ❖ Describe the challenges in teaching the multiply disabled ❖ Highlight the importance of early intervention for visually impaired children with multiple Concept and Definition of VIMD 5.3 Concept and Definition of VIMD 5.3.1 Concept When a child has several different disabilities we say, that he/she has multiple disabilities. For example, a child may have difficulties in learning, along with controlling her movements and / or with hearing and vision. The effect of multiple disabilities can be more than the combination of two individual disabilities. Provision of educational services are needed for those children with multiple disabilities whose cognitive functions are intact whereas only rehabilitation services can be planned for those whose cognitive functions are poor. Individual assessment is imperative for planning the educational programmes for these children. These children and youngsters are excluded from formal education due to their multiple disabilities. Sometime "exclusion" is as hard and cruel as it sounds: the school simply closes its doors for these children. However, more times the school does not know about the child before the school could get involved, others consider the situation too complicated or can not expect that the child might profit from formal education. 5.3.2 Definition A visually impaired child who has two or more disabilities concurrently that together constitute the so-called multiply disabled. There are many visually impaired children with one or more additional! associated disabilities. Characteristics The main characteristics of multiply disabled visually impaired children are:

172 a) They are different from others and need special programmes. b) They face more problems than others and need some help and can be included in regular school programmes with assistance and supportive devices. 5.3.3 Types of Additional Disabilities In order to develop programmes for the multi- disabled visually impaired children we classify them into four categories on the basis of their disabling conditions: 1. Deaf blind (Visual impairment+ hearing impairment) 2. Visual impairment + hearing impairment + mental retardation 3. Visual impairment + mental retardation. 4. Visual impairment + cerebral palsy + mental retardation/ hearing/ speech problems. 5.3.4 Current status of Education of Visually Impaired Children with Multiple Disabilities. The concept of specialized services to- children with multiple disabilities is relatively new in our country. The few services, which we can count on our fingertips, are located mostly in urban areas and can accommodate at the most a few hundred children. Services to young babies (0-6 years) are hardly available at present. Apart from non- availability of services, there are a number of areas of concern of such children, namely: ❖ A large population lives in remote rural areas where even the available basic health and education services are negligible. ❖ While the services for such children with multiple disabilities are almost non- existent, number of such children is consistently increasing due to the advancement of medical science. ❖ Moreover, most of such children do not reach these centres in time as parents are pursuing curative options in the crucial six years of the child's life. So a lot of learning that could have taken place gets delayed. ❖ Our policy makers, administrators and planners, adopted a pragmatic approach for the meaningful education of disabled persons. Nevertheless, as compared to the western countries, we are still lagging behind in the field of education

173 of multiply disabled children owing to a number of problems and limited resources. Some of the reasons for lack of tangible services to these children are cited below: ❖ Since the visually impaired child with additional disabilities requires a specialized training which is highly individualized and need based, this necessitates a right approach and availability of highly trained, skilled and dedicated professionals in different disciplines. The availability of such manpower in India at present is inadequate due to lack of proper training facilities for educators and other supportive staff. ❖ The teacher preparation in the area of disability at present is mostly focusing on the single disability area. As a result there are large number of single special teachers who can teach single disability but very few of them can teach children with additional disabilities. Because of the absence of trained teachers for teaching visually impaired children with additional disabilities, this area remained low priority area for many years in our country. ❖ The scattered population of visually impaired children with additional disabilities is another reason for not getting services timely. The residential facilities are inevitable for these children. But such facilities are hardly available to serve these children under education. ❖ Another problem is that these children do not seem to suit the schools where they are placed. Often parents of visually impaired child with additional disabilities are not able to identify which disability among the disabilities present in the child is more dominant. For example, the parents are perplexed whether the visually impaired mentally retarded child can be placed in a class with sighted mentally retarded or in a school for visually impaired. Because of the confusion the parents of these children do not bring them to the educational programmes. The principle that should be followed in case of such children is that a child with a dominant condition of visual impairment should be placed in a setting suitable for visually impaired children, while where the dominant disability is Mental Retardation; he/ she should be placed in the schools for mentally retarded children.

5.4 Etiology of VIMD

Multiple disabilities are quite multiple and diverse in nature and are found to possess more dissimilarities than the similarities or commonness observed among 174 them. Each of them has a different story of its causation, symptoms and challenges provided to the sufferer. It is therefore, quite difficult to name certain type of causes or causative factors responsible for the germination and perpetuation of all types of visually impaired with multiple disabilities among the children. However we can try to have the search for all the possible situations or factors that may be held responsible for bringing some or other types of impairments or disabilities in the mind and body of the children right from the time of their conception in the womb of the mothers in the following manner.

5.4.1 Factors Operating at the time of Conception (Genetic Factors)

There may go many things at the time of conception of the child in the womb of the mother through the transfer of genes and chromosomes to the offspring by the immediate parents that may work as a cause for providing disabilities among the children. A few of them are narrated.

- Chromosomal abnormalities may bring many disabilities and disorders among the children. The most frequent chromosomal abnormality is non-disjunction (unequal division) of chromosomes, and the most common clinical consequence is down syndrome. Children with this condition have 47 chromosomes instead of the normal 46. This extra chromosome may be provided by one of the parents, mother or father. Down syndrome may also be caused by abnormal translocation of chromosome. Hence the child has 46 chromosomes, but a pair of one is broken and the broken part is fused to another chromosome.
- Non -disjunction or unequal division of sex chromosomes may also provide a cause for a number of disabilities or disorders. The most common example is Klinefelter Syndrome. The males with this syndrome are born with an extra X chromosome derived usually from the mother. Many physical and mental abnormalities may be the product of this syndrome.
- Turner's Syndrome which affects girls is caused through the chromosomal loss. Girls with Turner syndrome have only single X chromosome and no second X or Y chromosome making a total of 45 rather than 46 chromosomes. As a consequence of the syndrome, they may have visual-perceptual impairments and sterility.
- Many abnormalities occur during chromosomal deletions. The examples are Cat Cry Syndrome (causing the individual to have a high pitched cry and

175 mental retardation) William Syndrome (causing mental impairments and physical deficits) and VCFS (causing mental impairments) Physical defects and language disabilities.) •••• In addition to the chromosomal abnormalities (extra or deleted chromosomal material) genetic disorders may also result from an abnormality in a single gene. Human genome (the set of all genes) approximately contains 1,00,000 genes. Out of this vast stock a single gene defect is quite capable of playing a primary role in about 7,000 disorders or disabilities (mckusic, 1986). These abnormalities may be passed down from one generation to the next. Examples of such single gene disorders are the formation of multiple neurofibroma tumors on the body and in the brain, Huntington disease or Fragile X-Syndrome neurological disorder), each capable of generating one or the other types of motor sensory cognitive and learning disabilities.

5.4.2 Factors Operating in the Womb of the Mother (Prenatal factors)

What goes wrong with the child during the embryologic and foetal development in the womb of his mother certainly prove a potent factor for the causation of one or the other disabilities in the child. A few of such major factors working in this direction may be outlined as follows:

- Maternal Chronic illness:** It has been found that a number of maternal chronic illnesses (during pregnancy) like thyroid disease, diabetes, hypertension and autoimmune disorders may adversely affect the growth and development of the child in the womb of his mother resulting into one or the other disabilities.
- Maternal infection:** A number of maternal infections like below are known to have devastating impact on the embryologic and foetal development. •••• Rubella also called as German measles is a highly contagious virus. If contracted by a mother during the first six weeks of her pregnancy, it may become a cause of havi ng risk to their foetus developing congenital rubella syndrome. The consequences of which may be the outcomes in the form of microcephally, mental retardation, cataract deafness and congenital heart defects. •••• Varicella (Chicken pox) caused by a DNA hyper virus is also a fatal maternal disease that adversely affects the developing foetus. Varicella infection, if contracted by a mother during the first 12 weeks of the pregnancy may cause 176 congenital defects in the developing foetus characterized by limb defects, scars, microcephaly, chorioretinitis and cataracts. •••• Sexually Transmitted Diseases (STDs) can cause severe complications for the developing foetus. The term STD stands for more than twenty five infectious organisms that are transmitted through sexual activity.
- Maternal substance abuse:** The intake of many substances by the mothers during pregnancy may cause a number of health hazards to the developing foetus like the following. •••• Many of the medications and drugs whether prescribed or non-prescribed may prove fatal to the developing foetus. As example we can name antiepileptic drugs (Used for seizure disorders). Methotrexate (used for treating cancer) and captoprial (used for treating chronic hypertension). More often, they are associated with congenital malformation such as heart defect, hearing, vision and mental retardation. •••• The intake of the substances like cocaine, heroin, marijuana and other illicit drugs by the pregnant mothers may cause high risk for the developing foetus causing foetal death, growth restriction, language disorders and emotional behavioural and attentional difficulties. •••• Maternal alcohol intake during pregnancy can have serious effect on the developing foetus. Most seriously it can result in Fotel Alcohol syndrome (FAS). The child with FAS has altered facial features, such as small head, widely spelled eyes, upturned nose, large ears and small chin, he or she will also have developmental problem such as oppositional and defiant behaviour, poor judgment and social withdrawal. Alcohol related birth defects make also one of the leading causes of mental retardation among many children. •••• Exposure to tobacco in the womb of the mother may prove quite fatal by bringing many respiratory problems, and sensory impairments to the developing foetus.
- Prenatal anoxia (oxygen deprivation):** This is resulted through a number of causes like maternal anemia, cord anomalies and the premature separation of the cord. It may be associated with a number of disability conditions like cerebral palsy, mental retardation, seizures, hearing and visual impairments and behavioural problems.

177 v) Prenatal cerebral haemorrhages: Resulted through a number of reasons like direct trauma, blood conditions of the mother and other causes, haemorrhage may produce a number of birth defects including cerebral palsy and mental retardation. vi) Prenatal exposure to radiation: Exposure to higher doses of radiation especially from the X-rays and radioactive substances involves a higher risk of congenital malformations, miscarriage, growth restriction and sensory impairments. 5.4.3 Factors operating at the Time of Birth (perinatal factors): There may be a number of things that may go wrong at the time of delivery causing a number of deficits and problems to the child like the following: i) Anoxia (Oxygen deprivation): The newborn baby may suffer from oxygen deprivation during prolonged labour or delivery for a variety of reasons like placenta separation from the uterus breech delivery (delivering feet first) etc. it can cause cells in the brain to die resulting in serious neurological impairments and as a consequence, the child may be affected by a number of disability. ii) Trauma and haemorrhage: Trauma and haemorrhage caused to newborn children during prolonged labour, sudden pressure changes, complicated delivery, caesarean delivery and mal positions may result into brain damage and neurological impairments. It may further result in various types of disability conditions. iii) Premature birth: Premature birth can be source of many problems and impairments to the newborn children. Their immature systems may make them quite vulnerable to infection and other chronic diseases. Moreover the underdevelopment of the brain may prove a potent factor for the causation of cerebral palsy, mental retardation and other accompanying sensory impairments. iv) Prenatal infection: The new born infants at the time of their birth may be subjected to a number of infections on account of the unhygienic conditions prevailed during delivery. It may lead to the development of many physical and mental impairments to the child. The most common infection affecting newborn at the stage may be named as varicella (Chicken pox), and cytomegalovirus (CMV). The newborn affected with CMV are found to manifest the symptoms of mental retardation, vision and hearing impairments and learning disabilities at the later stage of their life. 5.4.4 Factors operating after the Birth (Post-natal factors): There are many factors prevalent in one's environment that may prove a potent

178 source of causing one or the other impairments of disabilities among the children after their birth. These may be briefly named as follows: i) Chronic diseases and infection: Chronic diseases like serious respiratory problems, heart diseases brain tumors, cysts, juvenile arthritis etc. may cause serious obstacles in the path of the developing children particularly related to their adjustment and education and thus may lead them to many physical emotional, social and learning disabilities. Similarly, there are a number of infections that can cause severe impairments to their physical, mental or learning functioning. The most common are meningitis and encephalitis that may cause damage to the brain resulting into a number of disability conditions like hearing and visual impairments cerebral palsy, mental retardation, epilepsy and learning disabilities. ii) Accidents: Accidents are always uninvited. These can happen to anybody at any time giving serious blows to brain, skull fractures, spinal cord injuries and loss of limbs, hearing and vision. Thus, accidental injuries may prove a quite big source for the generation of many multiple disabilities to the children at the post-natal stage. iii) Radiation and Toxic agents: Exposure to radiation and radioactive elements as well as toxic chemicals like arsenic, lead, coal tar derivatives and carbon monoxide and carbon dioxide gas may be associated with a number of disabilities like cerebral palsy, mental retardation, eye and ear problems and learning disabilities etc. iv) Malnutrition: Mothers suffering from inadequate nutrition and starvation, may bring serious difficulties to their breast fed infants and children below the critical age leading to one or the other impairments at the later stage. v) Child abuse: In many cases, child abuse may be found a causative factor for generating one or the other types of disability among the children. Child abuse can result in broken bones, head trauma, spinal cord injuries, oxygen deprivation due to strangulation, severe eye and ear injuries, etc. all leading to one or the other type of physical mental and sensory impairments. Besides this, it can provide a germinating and perpetuating base for the ignition of social, emotional and behavioural problem among the abused children. vi) lower socio-economic status or poverty: Poverty may be associated with a number of disabled conditions in terms of their generation as well as perpetuation. The story may well begin with the malnutrition and almost starving conditions of the pregnant mothers, the most unhygienic and uncared delivery of the children and

179 inadequate supply of the essentials needed for the children's early development. Lack of medical care and treatment may further aggravate the problems and the child may develop serious limitations and deficiencies in terms of his adequate physical, mental, emotional and social development ultimately making the child retarded and disabled in so many aspects.

5.5 Impact of VIMD on learning and development

5.5.1 Where should children with VIMD be taught?

While emphasizing the need and importance of education to the children with VIMD Sailor (1991) writes "There is a single process called 'education' and it is delivered through the vehicle of the local school". In this way, in the opinion of many educators, neighbourhood school may prove a better placement alternative for the education of the multiple disabled children. It is least restrictive in all sense besides being quite accessible to all children irrespective of their socio-economic status and geographical location. Such access to least restrictive environment in terms of integrated settings of the neighbourhood school may prove to the welfare and progress of the children with VIMD. Most of the developed countries have come up with legislative provision to have the education of the multiple disabled in the integrated setting of the normal schools along with their non-disabled peers. It further states that special classes separate schooling or other removal of children with disabilities from the regular educational environment occurs only if the nature or severity of the disability is such that education in regular classes with the use of supplementary aids and services cannot be achieved satisfactorily. The same also holds quite practicable in the case of the children with all types of disabilities in our country. We cannot achieve the target 'the education of all (Sarv Shiksha) without adopting integration or inclusion as the main philosophy of our placement option for a huge scattered population of our disabled children. It is neither possible nor practicable to have segregated setting or special schools for each category of multiple disabled children. At present, we have some schools for a few special disabled categories like deaf and dumb, mentally retarded, cerebral palsy, and blind in our country. But we have a large number of diverse categories of multiple disabled (e.g. mentally retarded with Visually Impaired, learning, emotional or physical impairments deaf or blind with physical, mental and emotional problems, etc). The

180 special schools meant for a particular category of disability cannot serve the purpose of the education of the children with multiple disabilities. Moreover, the number of such special schools meant for a few special categories of disabilities are quite meagre and inaccessible to the vast majority of the disabled children population of our country. In such circumstances the integrated set-up of the regular class rooms of the neighbourhood schools is the only proper first alternative available for the educational placement of the disabled children (including multiple disabled) in our country. A few of such things concerning the adaptation and support are mentioned.

- Adaptations in the classrooms, work situations, drinking and toilet facilities and other learning, playing and recreational places for the needed mobility and positioning of the multiple disabled students.
- Educating and equipping the class teachers with essential knowledge, skills and attitudes (through pre-service or in service education) for teaching and dealing with the multiple disabled children.
- Arranging the aids and devices that are helpful in the teaching of multiple disabled children.
- Making use of the related services like counselling, physiotherapy, medical services, orientation and mobility services, etc.
- Seeking the service of the special education expert and professionals for providing needed assistance and guidance to the class teachers.

5.5.2 Curriculum considerations for Visually Impaired children with Multiple Disabilities VIMD:

After making decisions about the placement alternative for the children with multiple disabilities, it becomes essential to make a decision about the type of experiences to be given to these children in an inclusive set-up of the normal classrooms and regular schools. Since VIMD students represent a quite wide spectrum of disabled conditions, therefore, it is quite a challenging task to seek inclusion of the students with disabilities in the general education curriculum. Depending upon the nature and severity of their impairments particularly related to the areas of physical and mental development, now it should be decided how a particular multiple disabled student will have access to the general education curriculum. Wehmeyer, has pointed out some or all of the following options for this purpose.

181 Curriculum adaptation: The students can participate in the general education curriculum, but may need modifications in the presentation of instruction, expected performance, response modes, changes in materials, and the like. Curriculum augmentation: The students need additional instruction or strategies to participated in the curriculum. Curriculum alternations: The students need additional content that is not found in the general education curriculum. Students with severe or multiple disabilities may need instruction in basic social communication, daily living, and motor skills that are not found in the general education curriculum. In view of the above observation, while paying a little more individual attention and use of assistive technology, many of the multiple disabled students may be well adapted to participate in the general education curriculum without further accommodation. There will remain some students who may need special considerations within or beyond the inclusive setting. The curriculum needs of the children with VMMD, then may be extended to the following beyond the general education curriculum or experiences meant for all the children; non-disabled or disabled. •••• Developing communication skills. •••• Developing behaviour skills for the improvement of challenging behaviour (like stereotype, self-injurious, aggressive and socially inappropriate behaviour) •••• Care skills (like feeding oneself, toilet habits, dressing, making motor movements and postures with or without assistance, grooming and personal hygiene). •••• Acquisition of leisure and recreational skills for participating and enjoying such activities. •••• Development of essential basic functional academic skills pertaining to reading, writing and arithmetic. •••• Development of the skills for using assistive devices, and technology for improving their functioning.

5.5.3 Methods and Techniques for meeting the curriculum needs of the children with VMMD To teach the children with multiple disabilities in a fully inclusive set-up or

182 partial and more special set-up is really a quite challenging task. All of them have their unique strengths and limitations and therefore, essentially needs individualized ways to provide instructions to them in an effort to respond to their unique learning characteristics resulting from their multiple disabilities. In general, we can have the following things into our consideration while providing useful learning experiences to them. 1. The beginning in this direction needs to be made by taking care of their seating arrangement in the classroom and other work situation both in the inclusive and partial inclusive settings. The necessary adaptation in this regard should always be made for the multiple disabled children in view of their disabled conditions. As far as possible, they should be seated close to the teaching and supervising places of their teachers and instructors. 2. The next task is related to the communication skills. Any process of instruction and interaction in the classroom requires a process of communication between the teachers and the students. To have such communication link is a bigger problem for the children with multiple disabilities and the biggest for the teacher/ instructors. Deaf-blindness: A method of total communication approach is now mostly used with the instruction of deaf-blind children. It involves the use of multimedia to teach and learn as per needs of the individual's disability conditions. For example, if a student has some residual vision, he may advised to use a powerful magnifier. Similarly the student with some residual hearing may be advised to make use of a powerful hearing aid besides communicating with finger spelling. In such cases, the use of other senses like touch, taste, smell and kinaesthetic awareness should also be made for supplementing information of his environment and fulfilling his curricular and extracurricular needs. However most of the instruction and communication with the deaf-blind children (especially when no significant residual vision or hearing capacity is available) is usually carried out with the use of tactile techniques involving the sense of touch. That is why, Braille proves a quite stable reading medium for the deaf-blind and the use of a dual communication board can help them properly indiscriminating the reception or expressive functions of responses from a communication partner. Mental retardation-deafness: On account of their cognitive impairment these children may experience a lot of difficulty in the learning of oral language. The main

183 focus in their instruction should therefore be on the teaching of sign language. However they should also be taught a bit of functional oral language with the help of total communication approach. Mental retardation-blindness: Learning Braille (a major source of communication and learning for, the blind) may pose a serious difficulty for these children on account of limited mental capacities. The use of the senses other than visual can be employed for the teaching of these children. It may involve the use of recorded metal activity based teaching, oral instructions, etc, as the way of teaching and guiding method for them. Blindness-cerebral palsy: Cerebral palsy may make the affected children unable to make use of their gross or finer movement of hands and other limbs for various instructional purposes. In some cases, it may also create problems in their speaking. Depending on their impairment thus the blind cerebral palsy affected children may not be able to make use of Braille. In such cases, they should be helped with the aural modes of learning, e.g. use of tape recorder, radio, speaking machine, etc. Deafness-cerebral palsy: On account of their problems with motor movements, speech and comprehension, etc., it will not be difficult to make use of gestures of sign language with the group of multiple disabled children. In these cases we have to rely on making use of sight as a mode of their instruction. The help of visual communication board assisted with mechanically operated movement techniques they can prove useful in their instruction. Thus in many cases of the children with multiple disabilities who are not going in use natural speech or who need an additional mode of communication to communicate effectively. We have to plan necessary for the use of augmentative system of communication (use of aids supplementing the existing vocal communication skills) and alternative system of communication (methods of communication used by a person without vocal ability.) therefore, adequate care should always be taken for teaching the use of these modes of communication to the multiple disabled children. 3. The next serious task is to help the children with multiple disabilities to learn and make use of the necessary other functional skills like daily living skills, social skills, recreational and leisure skills, vocational skills, academic skills, behaviour management skills, etc. Like their non-disabled peers, the children with multiple disabilities may not be capable of learning the above mentioned functional skills through a mere imitation, observation or verbal instruction. 4. Whenever needed, the students with multiple disabilities should be allowed to 184 have a facilitator who can provide physical support to assist the students who cannot speak or whose speech is limited to typing on a key board or pointing at pictures, words or other systems on a communication board. 5. Students with multiple disabilities should be provided such learning experiences or made to participate in such activities that are provided to the same-age peers without disabilities. The methods and techniques used for providing them necessary learning experiences should be as appropriated as possible. 6. There may be proper provision for incorporating choice making activities into the classroom programmes for providing needed learning experiences to the students with VIMD. 5.6

Screening, identification and assessment of Visually Impaired Children with associated disabilities 5.6.1:

Screening Prenatal Screening: A number of prenatal testing procedures such as testing of maternal serum AFP, Multiple Marker Screening, chorionic villous sampling, Amniocentesis, Ultrasound, and Fetoscopy are available to detect the disorders of the foetus. On the basis of the results of screening appropriate corrective steps to prevent intellectual disability should be taken on the advice of a qualified physician. The following screening should be done: (i) Blood Tests in the Mothers Haemoglobin levels (Hb %) to detect anaemia. •••• Blood glucose levels to detect diabetes •••• Blood VDRL to detect syphilis •••• Blood group and Rh typing for blood group incompatibilities •••• Blood antibody titers to detect specific infections •••• Alpha foetus-proteins to detect neural tube defects in the foetus (ii) Ultrasonography (During Pregnancy) Many types of foetal pathology including those associated with VIMD later one can be indentified during the" trimester of pregnancy by means of ultrasound technique. Some of them are neural tube defects, such as hydrocephaly, microcephaly, and some cerebellar lesions.

185 (iii) Maternal Serum AFP (Alpha-fetoprotein) Maternal serum AFP (Alpha-fetoprotein) screening test is used to detect spina- bifida, anencephaly, Down's syndrome and other disorders. It is specifically targeted to women under age 35. The testing, which measures the amount of alpha-fetoprotein from foetal urine, takes place at 16-18 weeks of pregnancy. (iv) Multiple Marker Screening Multiple Marker Screening measures alpha-fetoprotein (AFP) and human chorionic gonadotropin (UE3). It enhances the effectiveness of screening for neural tube defects (NTD), Trisomy-21 or Down Syndrome, and Trisomy-18. It is done by a blood test that is offered to women between the 15th and 20th week of pregnancy. (v) Chorionic Villous Sampling Chorionic Villous Sampling or CVS can be used as early as the seventh to ninth weeks of pregnancy. It identifies Down syndrome and other birth defects. In CVS, a tiny piece of the chorionic villous tissue is removed. This tissue grows from an enveloping membrane that eventually gives rise to the placenta. It will show chromosomal abnormalities carried by the foetus. (vi) Amniocentesis: Amniocentesis is used to detect certain birth defects during the 15th week of pregnancy. Amniocentesis is a test performed on high -risk women. It involves the withdrawal of a sample of fluid surrounding the foetus. This fluid is then tested for possible abnormalities. The test is usually advised to women who have reached 35 years of age. Amniocentesis will detect Down syndrome, Tay-sachs, Sickle cell anaemia, and many other genetic disorders. The test increases slightly the risk of miscarriage. (vii) Ultrasound: Ultrasound is another pre-natal technique. It uses high frequency sound waves to locate the position and measure the size and structure of the foetus and placenta in the womb. Ultrasound is also used during amniocentesis to help guide the needle insertion. This technique can rule out foetal abnormalities such as faulty structure of the heart. (viii) Fetoscopy: Fetoscopy is an experimental technique used to observe the foetus. A viewing instrument is inserted into the womb. Neonatal and Post-natal Screening and Diagnostic Procedures

- APGAR score
- Urine screening for metabolic errors- example, PKU (Pheny)

186

- Blood biochemistry tests for Cretinism, Rickets, Jaundice etc.
- Blood antibody titers to detect infections
- Chromosomal analysis for Down Syndrome, Deletion syndromes etc.
- Neonatal neuro - behavioural assessments
- EEG (electro-encephalogram) for seizure disorder
- Visual screening for Visual Impairment (Visual acuity, fundus examination, retinoscopy etc)
- Auditory screening - hearing impairments (Tympanogram, BERA etc.)
- Ultra Sonogram
- Ct Scan(Computerised tomography)
- MRI (Magnetic Resource Imaging) for intracranial pathology and structural abnormalities.

5.6.2: Identification and Assessment of Multiple Disabilities The early identification and diagnosis of multiple disabilities among the children always serves the best purpose in the interest of the disabled children. By following the rule, "earlier the better", therefore, beginning should be made for their identification at the prenatal stage. At the "prenatal stage" the developing foetus may be screened for the possible disabilities by making use of the tests like the following: i. Alpha-fetoprotein test: In this test, a blood sample of the mother is taken after sixteen weeks of pregnancy for diagnosing some disabilities in the developing foetus (with an assumption that the foetus will pass sub-stances carrying symptoms of disabilities in the blood stream of the mother). With such a test, we can detect mother who are at risk of having a foetus, with neural tube defect (a defect involving the spinal column or brain), Down Syndrome, or some other birth defects (Batshaw and Perret, 1992). ii. Magnetic Resonance Imaging (MRI): MRI through its ultra fast imaging sequence can prove a valuable asset in the proper diagnosis of defects and impairments. For example, MRI of a central nervous system helps to identify the malformation of the brain seen in spinabifida and the cause of enlarged ventricles (hydrocephalus).

187 At the "post-natal stage" the newborn infants may be subjected to some specific tests like the following for the identification for the possible disabilities. 1. APGAR Scoring System: Known as APGAR test, it is the first screening that can be done to the newborn after their birth between one and five minutes. It takes into account the infant's heart rate, respiratory effort muscle tone, reflex irritability and skin color. Each of these five components of the Apgar test is scored between 0 and 2, with a maximum total score of 10. The below average score (less than 5) may provide an alert for something wrong with the child. The perception of the colour of the skin may also provide a vital clue such as Jaundice may be detected by a yellow caste to the skin and eyes. 2. Other Medical Examination and Observations: The other useful medical test and observations can be properly administered to the newborns and infants for the detection and diagnosis of a number of disabled conditions like the following. •••• Phenylketonuria (PKU) causing toxic accumulations of phenylalanine in the brain (a major cause of multiple disabilities) can be detected by a simple blood test of an infant preferably of one or two weeks old. •••• Blood and urine test can be carried out for the detection of hypothyroidism (the failure of the thyroid gland to function) which is known to cause cretinism an irreversible condition of severe mental retardation. •••• The blood test of the mother and the newborn can help in detecting Rh incompatibility known to cause a number of disabilities including cerebral palsy and mental retardation. •••• Help of EEGs combined with either videotape or direct observation may be taken for the identification of seizures in the infants at their neonatal and post-natal stages. •••• Similar to the Apgar score another scoring system exists for the detection of hypoxic ischemic encephalopathy. It is known as the Sarnat scoring system which can be followed by a (T or MRI scan (neuro imaging procedures) for accurate diagnosis. Hypoxicischemic encephalopathy if undetected and untreated earlier may give birth to a number of disabilities and health hazards like strokes, generalized atrophy in the brain, dyskinetic cerebral palsy, mental retardation and learning disabilities. •••• The direct clinical observation of the infants may prove helpful in the 188 identification of a number of disabled conditions. Most of the hearing and visual defects, motor deficits, mobility and physical impairments can be diagnosed early by observing the infant's lack of normal reflex and body movement. The other major defects and deformities like spinabifida (known for causing a number of multiple disabilities) can also be detected with the help of a close clinical examination). 3. Use of additional testing and collection of Data: After suspecting one or the other disabilities in the growing child, efforts are made to have surety of the suspected screening along with its full assessment by adopting the measures like the following: •••• Use of intelligence tests. •••• Use of adaptive behaviour scales •••• Use of interesting inventories, attitude scales, aptitude tests and personality interviews •••• Use of case history and medical report of the mother and the child •••• Use of the techniques and measures for the assessment of motor, communication, language, self-help, social and emotional abilities of the children. •••• Use of observation, rating scale and situational tests •••• Seeking interviews with the parents and teacher about their experiences with the child's inabilities and strengths. 5.7 Multidisciplinary assessment of visually Impaired Children with Associated Disabilities 5.7.1 What is Multidisciplinary Assessment? The individuals with Disabilities Education Act (IDEA) requires that children with developmental delay or disabilities receive a timely, comprehensive, multidisciplinary evaluation and assessment. The purpose of the assessment is to find out : The nature of your child's strengths delays, or difficulties, and Whether or not the child is eligible for early intervention services.

189 Multidisciplinary means that the evaluation group is made up of qualified people who have different areas of training and experience. Together, they know about children's speech and language skills, physical abilities, hearing and vision, and other important areas of development. They know how to work with children, even very young ones, to discover if a child has a problem or is developing within normal ranges. Group members may evaluate the child together or individually. Assessment refers to the procedures used by these professionals to find out if the child is eligible for early intervention services. As part of the Assessment, the team will observe the child, ask the child to things, talk to the parents and the child, and use other methods to gather information. These procedures will help the team find out how the child functions in five areas of development: cognitive development, physical development, communication, social-emotional development, and adaptive development. Following the child's assessment, the parents and a team of professionals will meet and review all of the data, results, and reports. The people on the team will talk with the parents about whether their child meets the criteria under IDEA and state policy for having development delay, a diagnosed physical or mental condition, or being at risk for having a substantial delay. The purpose of these on going procedure are to identify the child's unique strengths and needs, and determine what services are necessary to meet needs. Hence, assessment in general is a process of collection of information about an individual or a group and taking a decision for that particular individual or group for future course of action.

89%

MATCHING BLOCK 112/112

SA

SEVI-31 with glossary for alignment.docx (D127037367)

Assessment refers to the process of gathering and analysing information in order to make instructional, administrative and/or guidance decision about or for an individual (Wallace, Larsen and Elksnin, 1992)

Definition of assessment focuses on three aspects: 1. Collection of information 2. Analysis of information 3. Making decision for instructional, administrative steps and guidance

Collection of information: Collection of information regarding the students includes information regarding his personal history, the past achievement, the environment he is living, the resources available within his reach and current performance in different skills. These information could be collected by: (a) taking personal history, (b) administering test, (c) observation of the students and (d) interview with the student, parents and caretakers etc.

Analysis of information: Information collected has to be analysed by the special educator or the professionals related to the student from different angles. A student's performance in specific areas may be due to deprivation of exposure or cultural factors. This factor has to be carefully understood by the special educator for decision-making for educational intervention.

Making Decision for Instructional, Administrative Intervention and Guidance: Assessment is being used for making a decision for placement in a particular class and for availing Government facilities and programming educational intervention for the student. Special Educators help in guiding the parents for future course of action to be taken for the student. Special Educational Assessment is the systematic process of gathering educationally relevant information about children with special needs to make legal and instructional decisions about the provision of special services. The special educator pursues information that relates to everyday concerns of the classroom. However, educational intervention is also part of an interdisciplinary effort to understand the handicapped student's learning problems. It is performed in conjunction with the work of the professionals, such as physicians, speech-language, and physical therapists. Educational assessment focus mainly on many areas of learning school, as well as any other factor affecting school achievement, Academic, language, and social skills are examined. Environmental factors may also be considered, along with analyzing the student's observable and measurable learning behaviour and learning strategies. Training the mentally retarded children needs detailed psychological and educational assessment. There have been efforts in developing many psychological test and educational test for conducting assessment for development of systematic intervention programme for the children with mental retardation.

5.7.2: Purpose of Assessment: Assessment is carried out for a specific purpose. Generally, assessment helps in either decision-making for administrative purpose or for remedial purpose. Especially, in special education services, there are a few purposes to be met through assessment. The purpose of assessment determines the types of assessment tools to be used, the method of assessment to be selected and the process of collection of information to

191 be conducted. Some of the purpose of assessment are listed below: 1. Initial screening and identification. 2. Determining eligibility. 3. Determination of current performance level and educational need. 4. Decision about classification and programme placement. 5. Determination and evaluation of teaching programmes and strategies. 6. Development of educational programme (Individual or group). 7. Monitoring student progress. 8. Evaluating the effectiveness of educational intervention programme.

5.7.3: Types of Assessment: Special Education Assessment involves collection of information relevant to educational need of the children. This includes personal data, educational performance, the resources, the family involvement in training and voluntary supports that could be gained for training mentally retarded student. For all these information, it is essential to collect information through different methods. These methods may be: (a) Formal (b) Informal

Formal: In this method, the information is collected by administering test/ behavioural scales/ checklist, interview or administering questionnaire. The information is collected through very structured situation. It needs lots of preparation for the tester or observer.

Informal: In this method, the information is collected through natural interaction between the subject and observer. As because the information is being collected in a natural situation, there is a chance of getting appropriate response from the subject. Different tests are constructed for assessment. Constructed tests also vary as per the process of construction. There are two types of tests. These are Norm Referenced Test and Criterion Reference Test. Norm Reference assessment and Criterion reference assessment are named on the basis of the test used in the assessment process. The details of these-assessment processes are given below:

Norm Referenced Assessment: Norm referenced assessment is the more traditional approach to assessment. These tests and measurement procedures involve test materials that are standardized on a sample population and are used to identify the test takers ability relative to other. It is also known as formal assessment.

192 Norm referenced assessment is defined as a procedure for collecting data using a device that has been standardized on a large sample population for a specific purpose. Every standardized assessment instrument will, have certain directions that must be followed. These direction specify the procedure for administering the test and ways to analyse and interpret the results and reporting them.

Criterion Referenced Assessment: Criterion referenced assessment is concerned with whether a student is able to perform a skill as per the criteria set, or not. In contrast to norm -referenced assessment, which compares one person's performance to other's, criterion referenced assessment compares the performance of an individual to the pre-established criteria. In criterion referenced test, the skills within a subject are hierarchically arranged so that those that must be learned first are tested first.

Continuous Assessment: Assessment is an ongoing process. In the process of special Education to the children with VIMD, their abilities are assessed periodically to plan the future training programme. Flow diagram of which is given below:

Assessment Programme Planning
Implementation
Evaluation
Suggested Modification

In the above diagram, evaluation is carried out after implementation of the programme to see the level of achievement compared to set criteria. Evaluation is restricted to the programme planned for the child. Assessment covers the other non-

193 planned area for training. Assessment after each year or after a particular period of training is inevitable for decision-making about the child.

- 5.8 Check your Progress
- 1) What do you mean by Screening?
.....
.....
 - 2) What is Identification?
.....
.....
 - 3) List out the general characteristics of VIMD
.....

.....
.....

..... 12) Brief the teaching strategies for VIMD.

.....
.....

..... 13) compare the current Educational status of Visually Impaired Children with Multi Disabled Children?

.....

..... 14) What are the purposes of assessment you find in your case of assessment for IP?

.....

..... 15) How do you classify the etiological factors of VIMD.

.....
.....

196 5.9 Let us Sum up The effect of multiple disabilities can be more than the combination of two individual disabilities. Such kind of children face problem with all types of muscle movement as well as seeing and hearing. There may go many things during conception in the womb through gene and chromosome transfer by the parents to the offspring, that may cause such disabilities among the children. With this back drop, it is seen that the status of education of these children is in the least priority. Hence provisions of intervention will do some extent improve their developmental skills, direct abilities and create a firm ground for future learning. The concept of specialized services to children with multiple disabilities is more or less new in India. This service are localised to urban areas only. Nevertheless, as compared to the western countries parts, we are still lagging behind in the field of education of these children. Apart of this one of the most pertinent issue hovering is often parents of such children are not able to identify.Which disability among the multiple disabilities present in the child is dominant? These confusion cause hindrances in path of their educational programmes. 5.10 References : 1. Mittal S.R. : Education of Children with Low Vision 2. <p>Refraction of Eye Refraction refers to the state of focus of the eye. It is the ability of the eye to bend light so that an image is focused on the retina. So, refraction is the deflection of light from a straight path through the eye by various ocular tissues, including the cornea, lens, aqueous humour, and vitreous body. 1.5.2 Concept of Refractive Error Error in refractive media, the eye gets unclear or blurring image. When there is a deviation in light rays from a distant object brought to a focus on the retina, the image that is formed on the retina appears blurred.</p> <p>SA SEVI-31 with glossary for alignment.docx (D127037367)</p>

of the world. The lack of economic development is a factor that aggravates the prevalence of visual impairment. For this reason, blindness prevention programmes must concern themselves not only with the elimination of avoidable blindness but also with concurrent economic development. The cost of rehabilitation and care provided to the visually impaired are the most obvious. Less apparent but just as significant however

Although the hands are a major perceptual organ, a blind infant has significant developmental delays in his ability to employ his hands functionally. Even at 5 months a blind infant's hands will be fisted and held at shoulder height. There will be no mutual fingering, no engaging at the midline. At this age, a sighted child practise coordinated reaching and transference of objects from one hand to another. This delay in hand utilization will result in delayed fine motor and gross motor development.

Construct of World The blind child has limited ability to coordinate and organize elements into higher levels of abstraction, and to verify the information. Therefore, he constructs a reality that is different from the sighted child's. The process of establishing concept- defining attributes and relationships is more problematic for the blind child and less accessible to guidance. The blind child is continually involved in problem solving, but this process, which is essential to future development, is more difficult and less rewarding for him. Object Permanence A stable visual field is the basis of object permanence and other conceptual tasks. Object permanence cannot be obtained by a blind child until he has the ability to reach for objects based on sound cue alone. It is acquired nearly a year later than in sighted children. Causal Relationship Since the results of actions cannot be seen, the blind child may not be motivated to action. He may not understand his ability to cause things to happen or to retain pleasurable stimuli. 87 Constancy Understanding how to align blocks or orient his hands on a page in order to duplicate a pattern will be difficult ifhe hasn't observed objects in various orientations to know that an object is the same regardless of its position in space. 3.6

<p>Independent Living Skills This area of the expanded core curriculum is often referred to as "daily living skills." It consists of all the tasks and functions persons perform, in accordance with their abilities, in order to lead lives as independently as possible. These curricular needs are varied, as they include skills in personal hygiene, food preparation, money management, time monitoring, organization, etc. Some independent living skills are addressed in the existing core curriculum, but they often are introduced as splinter skills, appearing in learning material, disappearing, and then re-appearing. This approach will not adequately prepare blind and visually impaired students for adult life. Traditional classes in home economics and family life are not enough to meet the learning needs of most visually impaired students, since they assume a basic level of knowledge, acquired incidentally through vision. The skills and knowledge that sighted students acquire by casually and incidentally observing and interacting with their environment are often difficult, if not impossible, for blind and visually impaired students to learn without direct, sequential instruction by knowledgeable persons. Recreation and Leisure Recreation and leisure</p> <p>SA SEVI-31 with glossary for alignment.docx (D127037367)</p>

As a part of the expanded core curriculum, orientation and mobility is a vital area of learning. Teachers who have been specifically prepared to teach orientation and mobility to blind and visually impaired learners are necessary in the delivery of this curriculum. Students will need to learn about themselves and the environment in which they move - from basic body image to independent travel in rural areas and busy cities. The existing core curriculum does not include provision for this instruction. It has been said that the two primary effects of blindness on the individual are communication and locomotion. The expanded core curriculum must include emphasis on the fundamental need and basic right of visually impaired persons to travel as independently as possible, enjoying and learning from the environment through which they are passing to the greatest extent possible. 96

Technology Technology is a tool to unlock learning and expand the horizons of students. It is not, in reality, a curriculum area. However, it is added to the expanded core curriculum because technology occupies a special place in the education of blind and visually impaired students. Technology can be a great equalizer. For the braille user, it allows the student to provide feedback to teachers by first producing material in braille for personal use, and then in print for the teacher, classmates, and parents. It gives blind persons the capability of storing and retrieving information. It brings the gift of a library under the fingertips of the visually impaired person. Technology enhances communication and learning, as well as expands the world of blind and visually impaired persons in many significant ways. Thus, technology is a tool to master, and is essential as a part of the expanded core curriculum.

<p>Career Education There is a need for general vocational education, as offered in the traditional core curriculum, as well as the need for career education offered specifically for visually impaired students. Many of the skills and knowledge offered to all students through vocational education can be of value to visually impaired students. They will not be sufficient, however, to prepare students for adult life, since such instruction assumes a basic knowledge of the world of work based on prior visual experiences. Career education in an expanded core curriculum will provide the visually impaired learner of all ages with the opportunity to learn first-hand the work done by the bank teller, the gardener, the social worker, the artist, etc. It will provide the student opportunities to explore strengths and interests in a systematic, well-planned manner. Once more, the disadvantage facing the visually impaired learner is the lack of information about work and jobs that the sighted student acquires by observation. Because unemployment and underemployment have been the leading problem facing adult visually impaired persons, this portion of the expanded core curriculum is vital to students, and should be part of the expanded curriculum for even the youngest of these individuals.</p>

Screen Reader/Speech Synthesizer Screen readers provide auditory feedback when using the keyboard as well as auditory access to information displayed on the monitor. These systems consist of a software programmes and speech synthesizer. The software programmes sends information from the computer to the synthesizer, where phonemes are combined into words and the words are spoken. Most systems allow choices in volume, voice quality and speed of output. Students with limited vision will find these devices useful, especially when connected to a regular printer for output (JAWS, Intellitalk, IBM ScreenReader/DOS). Voice Access Voice access systems allow the user to interact with the computer screen by using voice commands instead of the keyboard. They are particularly useful for students who have difficulties with fine motor control as well as visual impairments. These systems include special software and sound cards to allow for voice output of information on the screen. As with screen readers, they can be connected to braille and regular printers for output (DragonDictate, Naturally Speaking). Scanner The scanner will scan print text of good quality. It must be used in conjunction with optical character recognition software. Then the scanned text can be

From the Vice-Chancellor's Desk Dear Students, from this Academic Session (2015-17) the Curriculum and Course Structure of B. Ed.- Special Education have been thoroughly revised as per the stipulations which featured in the Memorandum of Understanding (MoU) between the Rehabilitation Council of India (RCI) and the National Council for Teacher Education (NCTE). The newly designed course structure and syllabus is comprehensive and futuristic has, therefore, been contextualized and adopted by NSOU from the present academic session, following the directives of the aforesaid national statutory authorities. Consequent upon the introduction of new syllabus the revision of Self Instructional Material (SIM) becomes imperative. The new syllabus was circulated by RCI for introduction in the month of June, 2015 while the new session begins in the month of July. So the difficulties of preparing the SIMs within such a short time can easily be understood. However, the School of Education of NSOU took up the challenge and put the best minds together in preparing SIM without compromising the standard and quality of such an academic package. It required many rigorous steps before printing and circulation of the entire academic package to our dear learners. Every intervening step was meticulously and methodically followed for ensuring quality in such a time bound manner. The SIMs are prepared by eminent subject experts and edited by the senior members of the faculty specializing in the discipline concerned. Printing of the SIMs has been done with utmost care and attention. Students are the primary beneficiaries of these materials so developed. Therefore, you must go through the contents seriously and take your queries, if any, to the Counselors during Personal Contact Programs (PCPs) for clarifications. In comparison to F2F mode, the onus is on the learners in the ODL mode. So please change your mind accordingly and shrug off your old mindset of teacher dependence and spoon feeding habits immediately.

I would further urge you to go for other Open Educational Resources (OERs) - available on websites, for better understanding and gaining comprehensive mastery over the subject. From this year NSOU is also providing ICT enabled support services to the students enrolled under this University. So, in addition to the printed SIMs, the e-contents are also provided to the students to facilitate the usage and ensure more flexibility at the user end. The other ICT based support systems will be there for the benefit of the learners. So please make the most of it and do your best in the examinations. However, any suggestion or constructive criticism regarding the SIMs and its improvement is welcome. I must acknowledge the contribution of all the content writers, editors and background minds at the SoE, NSOU for their respective efforts, expertise and hard work in producing the SIMs within a very short time. Professor (Dr.) Subha Sankar Sarkar Vice-Chancellor, NSOU

Unit - 1 Curricular and It's Designing Structure 1.1 Introduction 1.2 Objectives 1.3

Curriculum-Concept, Types and Models 1.4 Approaches and Steps for Curriculum Designing 1.5 Curricular Needs of children with hearing impairment in Scholastic Areas. 1.6 Curricular Needs of children with hearing impairment in Non-Scholastic Areas. 1.7 Curricular Framework for 21 st Century 1.8

Let us sum up 1.9 Check your progress 1.10 References 1.1 Introduction Education for All is a universal dream. All the modern nations are trying their best to actualize this dream. Special attention is being provided to conventional known weaker links in the chain of education, self reliance, prosperity and development. These 'marginalized' groups which were untouched by education until very recently are now entering the mainstream education. We need to make our system more accommodative, flexible and warm, so that these groups not only enter the conventional classrooms but also make these classrooms more colorful and rich. Changes are being made towards this purpose. New ideas, modern technology and broad minded philosophy are being passed down from international to national level from national to state level and from state level to schools. Among the disabilities, hearing disability has a unique situation which may make the inclusion process slower and difficult. With other disabilities, in general, language and communication are not the primary concerns. With individuals with hearing impairment, this is not the case.

10 Inadequate language and communication have the potential to negatively impact almost all developmental aspects of a child. Moreover, if not dealt with carefully, hearing impairment may delink the child not only from the society but also from the family. You yourself can think of the serious concerns created by such a situation. This unit is named as Curricular and It's Designing and delineates five sub-units. These are Curriculum-Concept, Types and Models, Approaches and Steps for Curriculum Designing, Curricular Needs of children with hearing impairment in Scholastic Areas. Curricular Needs of children with hearing impairment in Non-Scholastic Areas and lastly Curricular Framework for 21 st Century. 1.2.

Objective: Upon completion of the unit, the learner will be able to- ? to know about the curriculum concept, type and different model. ? to Understand different

approaches and steps for curriculum designing. ? to explain the curricular needs of children with hearing impairment in scholastic areas. ? to delineate the curricular

needs of children with hearing impairment in non-scholastic areas. ?

To know about the curriculum framework for 21 st century 1.3 Curriculum-Concept, Types and Models Definitions of Curriculum In Education

curriculum is broadly defined as the totality of student experiments that occur in the educational process.

The term often refers specifically to a planned sequence of instruction or its view of the student's experiences in terms of the educator's or schools instructional goals. Curriculum is to incorporate with

the planned interaction of pupils with instructional content, materials, resources and processes for evaluating of educational objectives.

The word "curriculum" began as a Latin word which means "a race" or "the course of a race" which in turn derives from the verb currere meaning "to run/to proceed".

In history of education, the term 'curriculum' was originally related to the concept of a course

11 of studies followed by a pupil in a teaching institution.

The concept of "curriculum" was used in the English-speaking tradition as equivalent to the French concept programme. In fact, the term curriculum is mostly used to refer to the existing contract between societies with regard to the educational experiences that learners should undergo during a certain phase of their lives.

For the majority of authors and experts, the curriculum defines: (i) why; (ii) what; (iii) when; (iv) where; (v) how; and (vi) with whom to learn. Using educational concepts, we can say that the curriculum defines the educational foundations and contents, their sequencing in relation to the amount of time available for the learning experiences, the characteristics of the teaching institutions, the characteristics of the learning experiences, in particular from the point of view of methods to be used, the resources for learning and teaching (e.g. textbooks and new technologies), evaluation and teachers' profiles. Originally, the curriculum was considered as the product of a technical process. In other words, as a document prepared by experts, depending on the state of the art of disciplinary and pedagogical knowledge. There is no generally agreed upon definition of curriculum. Some influential definitions combine various elements to describe curriculum as follows: ? Jhon

Kerr, 1966 defines curriculum as, "

All the learning which is planned and guided by the school, whether it is carried on in groups or individually, inside or outside of school.” ?

Braslavsky, 2003 states that curriculum is an agreement amongst communities, educational professionals, and the State on what learners should take on during specific periods of their lives. Furthermore, the curriculum defines “why, what, when, where, how, and with whom to learn Some cumulative definition are as follows: ? Outlines the skills, performances, attitudes, and values pupils are expected to learn from schooling. It includes statements of desired pupil outcomes, descriptions of materials, and the planned sequence that will be used to help pupils attain the outcomes. ? The total learning experience provided by a school. It includes the content of courses (the syllabus), the methods employed (strategies), and other aspects, like norms and values, which relate to the way the school is organized.

12 ? The aggregate of courses of study given in a learning environment. The courses are arranged in a sequence to make learning a subject easier. In schools, a curriculum spans several grades. ? Curriculum can refer to the entire program provided by a classroom, school, district, state, or country. A classroom is assigned sections of the curriculum as defined by the school. ? Curriculum is such “permanent” subjects as grammar, reading, logic, rhetoric, mathematics, and the greatest books of the Western world that best embody essential knowledge. ? Curriculum is those subjects that are most useful for living in contemporary society. ? Curriculum is all planned learning for which the school is responsible. ? Curriculum is all the experiences learners have under the guidance of the school. ? Curriculum is the totality of learning experiences provided to students so that they can attain general skills and knowledge at a variety of learning sites. ? Curriculum is what the student constructs from working with the computer and its various networks, such as the Internet. ? Curriculum is the questioning of authority and the searching for complex views of human situations. ? Curriculum is all the experiences that learners have in the course of living. 1.3.1-Procedure of Curriculum ? Step 1: Diagnosis of needs Example: Diagnosis of the hearing impaired child about the language potential skill. ? Step 2: Formulation of objectives Example:Set goals for the development of language potential skill. ? Step 3: Selection of content

13 Example: After acquiring the language, he/she will be able to writes psychomotor /hand skills and express the idea about the language with the help of Cognitive / head-knowledge. ? Step 4: Organization of content Example:Language should be represented as per Chronological order, Maintain content sequence, Causes and effect and Structural logic. ? Step 5: Selection of learning experiences Example:The language learnt in the class rooms and it has to be carried forward, transferred and enhanced outside the classroom situation too. ? Step 6: Organization of learning experiences Example:Teacher can plan activities which are of the child’s interest and should match with the current trends like taking about the picture, different activities, etc. ?

Step 7: Determination of what to evaluate and of the ways and means of doing it.

Example:Teacher should maintain teaching language with the hearing impaired children to use the strategies like modeling, correction and speech teaching. 1.3.2-Types of curriculum

Anything and everything that teaches a lesson, planned or otherwise.

Humans are born learning thus the learned curriculum actually encompasses a combination

of all of the following the hidden, null, written, political and societal etc. Since students learn all the time through exposure and modeled behaviors this means that they learn important social and emotional lessons from everyone who inhabits a school from the staff, the secretary, peers as well as from the department, conduct and attitudes expressed and modeled by their teachers.

14

The following represent the many different types of curricula used in schools today: Type of Curriculum Definition It is simply that which is written as part of formal instruction of schooling experience. It may refer to a curriculum document, texts, films, and supportive teaching materials that are overtly chosen to support the intentional instructional agenda of a school.

Thus, the written curriculum is usually confined to those written understandings and directions formally designated and reviewed by administrators, curriculum directors and teachers, often collectively. As defined by Cortes (1981). Cortes defines this curriculum

is a

massive, ongoing, informal curriculum of family, peer groups, neighbourhoods, churches organizations, occupations, mass media and other socializing forces that “educate” all of us throughout our lives.

This type of curricula can now be expanded to include the powerful effects of social media.

That which is implied by the very structure and nature of schools, much of what revolves around daily or established routines. Longstreet and Shane (1993) offer a commonly accepted definition for this term the "hidden curriculum," which refers to the kinds of learning children derive from the very nature and organizational design of the public school, as well as from the behaviours and attitudes of teachers and administrators. Examples of the hidden curriculum might include the messages and lessons derived from the mere organization of schools the emphasis on: sequential room arrangements, timed segments of formal instruction,

disciplined messages where concentration equates to student behaviours were they are sitting up straight and are continually quiet, students getting in and standing in line silently, students quietly raising their hands to be called on the endless competition for grades and so on. The hidden curriculum 1.

Written Curriculum 2. Social Curriculum 3.

The hidden or covert curriculum

15 may include both positive and negative messages depending on the models provided and the perspectives of the learner or the observer. That which we do not teach, thus giving students

the

message that these elements are not important in their educational experiences or in our society. Eisner offers some major points as he concludes his discussion of the null curriculum.

Eisner (1985, 1994) first described and defined aspects of this curriculum. He states that something of a paradox involved in writing about a curriculum that does not exist.

From Eisner's perspective the null curriculum is simply that which is not taught in schools. Somehow, somewhere, some people are empowered to make conscious decisions as to what is to be included and what is to be excluded from the written curriculum. Since it is physically impossible to teach everything in schools, many topics and subject areas must be intentionally excluded from the written curriculum.

But Eisner's position on

the "null curriculum" is that when certain subjects or topics are left out of the overt curriculum school personnel are sending messages to students that certain content and processes are not important enough to study. Unfortunately, without some level of awareness that there is also a well-defined implicit agenda in schools, school personnel send this same type of message via the hidden curriculum.

These are important to consider when making choices. We teach about wars but not peace, we teach about certain select cultures and histories but not about others. Both our choices and our omissions send messages to students. The messages prevalent in and through

exposure to any type of media. These components and messages play a major part in the enculturation of students into the predominant meta-culture or in acculturating student

into narrower or generational sub-cultures. What is taught, or emphasized at home, or those experiences that are part of a family's experiences, or related experiences sanctioned by the family. This type of curriculum may be received in the different

context of religious expression, lessons on values, ethics or morals, 4.

The null curriculum 5. Phantom curriculum 6. Concomitant curriculum

16

moulded behaviours or social experiences based on the family's preferences. Elements from the rhetorical curriculum are comprised from ideas offered by policymakers, school

officials, administrators, or politicians. This curriculum may also come from those professionals involved in concept formation and content changes or from those educational

initiatives resulting from decisions based on national and state reports, public speeches

or from texts critiquing outdated educational practices. The rhetorical curriculum may also come from the publicized works offering updates in pedagogical knowledge. The formal curriculum (written or overt) comprises those things in textbooks, and content and concepts in the district curriculum guides. However, those "formal" elements are frequently not taught. The curriculum-in-use is the actual curriculum that is delivered and presented by each teacher. Those things that

students actually take out of classrooms those concepts and content that are truly learned and remembered.

Processes, content and

knowledge combined with the experiences and realities of the learner to create new knowledge. While educators should be aware of this curriculum, they have little control over the internal curriculum since it is unique to each student.

Educators can explore this curricula by using instructional assessments like "exit slips," reflective exercises, or debriefing discussions to see what students really remember from a lesson. It is often very enlightening and surprising to find out what has meaning for learners and what does not.

Those lessons learned through searching the Internet for information, or through using e-forms of communication. This type of curriculum may be either formal or informal, and inherent lessons may be overt or covert, good or bad, correct or incorrect depending on

one's' 7. Rhetorical curriculum 8. Curriculum- in-use 9. Received curriculum 10. The internal curriculum 11. The electronic curriculum

17

views. Students who use the Internet on a regular basis, both for recreational purposes (as in blogs, wikis,

chatrooms, list serves, through instant messenger, on-line conversations, or through personal e-mails and sites like Twitter, Facebook, or Youtube) and for personal online research and information gathering

are bombarded with all types of media and messages. Much of this information may be factually correct, informative, or even entertaining or inspirational. But

there is also a great deal of other e-information that

may be very incorrect, dated, passé, biased, perverse, or even manipulative. The implications

of the electronic curriculum

for educational practices are that part of the overt curriculum needs to include lessons on how to be wise consumers of information, how to critically appraise the accuracy and correctness of e-information, as well as

how to determine

the reliability of electronic sources. Also, students need to learn how to be artfully discerning about the usefulness and appropriateness of certain types of information. Like other forms of social interaction, students need to know that there are inherent lessons to be learned about appropriate and acceptable "netiquette" and online behaviors, to include the differences between "fair and

legal usage," vs. plagiarism and information piracy. In learner centered curriculum there is a link between courses and children psychology. It is according to the interest and tendency of children. It facilitates the mind of children because it fulfills their psychological and mental requirements. In 18th century "Rolso" highlight the importance of individual needs and interest of students. After "Rolso", it was "Pestalozzi" and "John Davi" who further enhanced the excellence of the concept. To know about this concept meaning that interest of student and to fulfill their needs was developed as the central part of the course by John Davi. More and more practical activities included so that children become able to take part with their own choice. Active Learning is in short, anything that students do in a classroom other than merely passively listening to an instructor's lecture. This 12. Learner Centered Curriculum 13. Activity Based Curriculum

18 includes everything from listening practices which help the students to absorb what they hear, to short writing exercises in which students react to lecture material, to complex group exercises in which students apply course material to "real life" situations and/or to new problems. According to Tanner and Tanner, "Activity curriculum is an attempt to treat learning as an active process. Activity curriculum discards the boundaries and the curriculum was centered largely on areas of child interest. The objective of curriculum was child growth through experience. According to Beans, "The major premise of activity movements was that learner ought to be active rather than passive participants in learning". ? Components of good active learning: ? A definite beginning and ending ? A clear purpose or objective ? Contain complete and understandable directions ? A feedback mechanism ? Include a description of the technology or tool being used in the exercise. Integrated curriculum is a learning theory describing a movement toward integrated lessons helping students makes connections across curriculum. The approach should be viewed as a tool that can help educate students and engage them in the learning process. Integrated curriculum is basically adding another element to existing materials or activities. What usually ends up happening is the child adds that element to their play or exploration and that stimulates more curiosity and possibilities, which exercises their thinking skills. According to Beane, 1995, "Educators seem especially interested in the development and use of curriculum integration as a means of increasing student interest and student knowledge". Whenever possible, teacher work to integrate many subject areas under a common theme when teaching. For example, the second grade unit about insects in science may include reading "Going to be a butterfly" for reading, and graphing students' favorite insects for math. Instead of seeing learning as separate subjects unrelated to each other, children gain a deeper 14. Integrated Curriculum

19 understanding of overall knowledge and how it all relates. Teachers of different subjects within an existing curriculum can determine collectively the extent to which other domains are addressed already in their teaching and learning programs. For example: Thinking, Interpersonal Learning, English, History etc. 'Core' refers to the 'heart' of experiences every learner must go through. Fundamental knowledge that all students are required to learn in school. A core curriculum is a curriculum or course of study which is deemed central and usually made mandatory for all students of a school or school system. This is not an independent type of curriculum. It refers to the area of study, courses or subjects that students must understand in order to be recognized as educated in the area. The learner has no option but to study the prescribed course or subjects. Educators defines of Core Curriculum "A core curriculum is a pre-determined body of skills, knowledge, and abilities are taught to all students". As in mathematics (in Arithmetic), all pupils need to acquire proficiency in addition, subtraction, multiplication, and division. It contains core or exact precise subject matter usable in society. The messages of hidden curriculum may support or contradict each other as well as the written curriculum. For example, while school social studies curriculum typically emphasizes and even celebrates democratic political systems and principles, such as one person- one vote, majority rule and minority rights, equality before the law and due process, these principles are not always practiced in public school classrooms and corridors. The collateral curriculum is designed intentionally to afford students the opportunity to learn empowering concepts, principles, and ideas peripheral or outside the subject being taught. Though the teacher intends learning outcomes for the collateral curriculum, the knowledge is not specified in the instructional objectives nor is it assessed. In this sense, the collateral curriculum is a planned hidden curriculum. 15. Core Curriculum 16. Hidden Curriculum 17. Collateral Curriculum

20 1.3.3-Models of curriculum To understand curriculum models we need to take a step back and talk about curriculum itself. Curriculum can be defined as a plan used in education that directs teacher instruction. Many schools use a tool designed to help teachers pace their lessons called a curriculum guide. But curriculum and a curriculum guide don't just come out of thin air. Time and energy goes into the creation of these documents. This process is known as curriculum development. It is clear that curriculum is the stuff teachers teach and they use a curriculum guide to help them decide what, when and how to teach it so both the guide and the stuff come from people who have developed or made up the material. All of these things are based on a curriculum model. A model is really the first step in curriculum development. A curriculum model determines what type of curriculum used and itemphasis educational philosophy, approach to teaching and methodology. That's why curriculum model is a format for curriculum design developed to meet unique needs, contexts and purposes. In order to address these goals, curriculum developers design, reconfigure or rearrange one or more key curriculum components and educators to be familiar with the models used in their schools. Key concept of curriculum components models The focus on concept of curriculum components and models to looks at a subject or a student and centres instruction on them.

The approach component is

a traditional or modern method and looks at the type of instruction that will be used.

The process structure looks at assessment formative or accumulative. Finally structure components focus on the system of review, determining how the curriculum will come up for revision. Product and Process Models: Curriculum models can be broken down into two very broad models. These are product model and the process model. ? Product Model - This model is focused on results, like grades or reaching an objective. The majority of the weight is focused on the finished product than what is happening in the learning process. ? Process Model - Conversely, this process model focuses on how things happen in the learning and is more open-ended. Curriculum focusing on the process model 21 emphasizes how students are learning, what their thinking is and how it will impact future learning. 1.3.4-Popular Curriculum Models 1.3.4.1-The Tyler Model- One of the best known curriculum models is The Tyler Model introduced in 1949 by Ralph Tyler in his classic book Basic Principles of Curriculum and Instruction in which he asked 4 questions: These are: ?

What educational purposes should the school seek to attain? ? What educational experiences can be provided that is likely to attain these purposes? ? How can these educational experiences be effectively organised? ? How can we determine whether these purposes are being attained? 1.3.4.2-

The Taba Model- Another approach to curriculum development was proposed by Hilda Taba in her book Curriculum Development. Theory and Practice published in 1962. She argued that there was a definite order in creating a curriculum. She believed that teachers,

who teach the curriculum, should participate in developing it which led to the model being called the grass-roots approach. She noted 7 major steps to her grass-roots model in which teachers would have major input. So seven major steps are: a. Diagnosis of need:

The teacher who is also the curriculum designer starts the process by identifying the needs of students for whom the curriculum is planned. For example, the majority of students are unable to think critically.

b. Formulation of objectives:

After

the teacher has identified needs that require attention he or she specifies

objectives to be accomplished.

c. Selection of content: The objectives selected or created suggest the subject matter or content of the curriculum.

Not only should objectives and content match, but also the validity and significance of the content chosen needs to be determined. i.e. the relevancy and significance of content. d. Organisation of content:

A teacher cannot just select content but must organise it in some type of sequence taking into consideration the maturity of learners their academic achievement and their interests.

22

e. Selection of learning experiences:

Content must be presented to students and students must be engaged with the content. At this point, the teacher selects instructional methods that will involve the students with the content. f. Organisation of learning activities: Just as content must be sequenced and organised, so must the learning activities. Often, the sequence of the learning activities is determined by the content. But the teacher needs to keep in mind the particular students whom he or she will be teaching.

g. Evaluation and means of

evaluation: The curriculum planner must determine just what objectives have been accomplished.

Evaluation procedures

need to be designed to evaluate learning outcomes. 1.3.4.3-The

Saylor and Alexander Model Galen Saylor and William Alexander (1974) viewed curriculum development as consisting of four steps. According to them,

curriculum is "a plan for providing sets of learning opportunities to achieve broad educational goals and related

specific objectives for an identifiable population served by a single school centre".

Four steps are I. Goals, Objectives and Domains: The model indicates that

curriculum planners begin by specifying the major educational goals and specific objectives they wish to accomplish. Each major goal represents a curriculum domain and they advocate 4 major goals or domains: personal development, human relations, continued learningskills and specialisation. The goals, objectives and domains are selected after careful consideration of several external variables such as findings from educational research, accreditation standards, views of community groups and others. II. Curriculum Designing: Once the goals, objectives and domains have been established, planners move into the process of designing the curriculum. Here decision is made on the appropriate learning opportunities for each domain and how and when these opportunities will be provided.

III. Curriculum Implementation: After the designs have been created the next step is implementation of the designs by teachers.

Based on the design of the curriculum plan teachers would specify instructional objectives and then select

relevant teaching methods and strategies to achieve the desired learning outcomes among students

23 in the classroom. IV. Evaluation: Finally, curriculum planner and teachers engage in evaluation. The model proposed that evaluation should be comprehensive using a variety of evaluation techniques. Evaluation should involve the total educational programme of the school and the curriculum plan, the effectiveness of instruction and the achievement of students. Through the evaluation process, curriculum planner and developers can determine whether or not the goals of the school and the objectives of instruction have been met. 1.3.5-Curriculum Models Frameworks There many curriculum model frame work are there. These are 1. Specific model 2. The Developmental Model 3. The Functional Model 4. The Ecological Approach Model 5. Subject/Teacher Centered Design 1. Specific model: Five broad categories can be used to define the focus of these models. These are: ? Subject or Discipline-Centered - In this framework, the curriculum is organized around subjects, like math or science. ? Integrated - Just like it sounds, this framework pulls many subjects together. We see this model used in problem based learning and experiential learning. ? Spiral - In this framework, the content is presented several times across the span of the school year. Seen mostly in math, using this design allows students to be introduced, and then revisit material, often. ? Inquiry or Problem Based - Not to be confused with integrated models, this curriculum focuses on a central problem or question. In this frame all curriculum is problem based, while in integrated it may or may not be. ? Experiential - Using this framework allows students to participate in real-life ways with their work, experimenting with hypothesis, working through problems and finding solutions.

24 2. The Developmental Model:

This model proposes that development of typical and atypical children progresses in a predictable sequence and that this sequence should be taught to students with disabilities. ? Weaknesses: ? First, time can be wasted working on skills which may never be mastered. ? Second, not all behaviors in the sequence are necessary for independent functioning nor are they age appropriate as the child grows well beyond the age that development skills are typically mastered. ? Finally, the child is viewed as "developmentally young". Consequently, the activities and materials used for intervention continue to be less than age appropriate which leads to negative perceptions and low expectations for children with severe disabilities. 3.

The

Functional Model:

The philosophy of this approach is that students with severe disabilities need to acquire age appropriate and functional skills (

i.e., skills necessary for functioning independently). ? Advantage & weakness: ?

It reflects higher expectations for students with severe disabilities and promotes opportunities to acquire age-appropriate skills. ? That there are not established criteria for determining what is functional and relevant for an individual student. 4.

The

Ecological Approach Model: The ecological approach reflects characteristics of both the individual student and the environments in which his or her participation is desired. The planning team using the ecological approach to curriculum development devises an individual curriculum which addresses the skills, activities, and environments most relevant to the student. The curriculum content is ever changing as the needs of the student change. ? Advantages ? It promotes teaching skills that are age-appropriate and relevant to the student's daily life, while it respects the need to teach skills in order of progressive refinement and complexity. ? It encourages the use of adaptations that accommodate the disability or simplify task demands.

25 The ecological approach also tends to unify team member efforts because the environments and activities that are identified as priorities for each student provide a natural context for integrating related services.

5. Subject/Teacher Centered Design: The subject centered curriculum is based on subject. All knowledge is transferred to student through the subjects. Subject matter taught should reflect basic areas that are essentials and agreed upon content for learner attainment. 1 Cognitive 2 Emotional 3 Environmental influences and 4 Experiences for acquiring, enhancing, or making changes in learner's a knowledge b skills c values d world views Objective- ? To transfer cultural heritage ? To represent knowledge ? To impart information

26 Limitation of subject centered curriculum- ? Ignores interest of students ? No process of insight or thinking ? Rote memory ? Neglects social problems and demands ? Passive learning

1.4 Approaches and Steps for Curriculum Designing Curriculum is a comprehensive plan for an educational training program course to offer new improved manpower to fulfill the rising needs of a dynamic society. The process of continuous course improvement, common to all education and training institutions, provides the framework for the approach to curriculum and course development proposed here.

1.4.1. Orientations to Curriculum Curriculum orientation is a personal belief about the purpose of education such as curriculum intent, content, organization, teaching methods, learning activities and instructional assessment of a curriculum (Cheung, 2000). Eisner and Vallance (1974) have proposed classification scheme consisting of five curriculum orientations these are academic rationalism, cognitive processes, social reconstruction-relevance, self-actualization and curriculum as technology and these five curriculum orientation relation to about the Child-centered, Society-centered, Knowledge-centered, Eclectic.

27 1.4.2-Steps to Curriculum Development There are six steps approaches are there. These are: 1. Problem Identification ? Identify and characterize the healthcare problem „ ? Know what we are talking about 2 Needs to Assessment of Learners ? Know who our target audience is and what our target audience needs 3 Goals and Objectives „ ? Identify the end toward which an effort is directed ? Goals ? Objectives – specific and measurable ask. ? Direct the choice of curricular content „ ? Clearly communicate the purpose „ ? Suggest what learning methods will be most effective 4 Educational Strategies ? Identify the educational strategies by which the curricular objectives will be achieved. Involve both content and method. „ ? Provide the means by which curricular objectives are achieved 5 Implementation ? Identify sufficient resources, support and others to successfully implement the curriculum. 6 Evaluation and Feedback ? Describe the plan to evaluate the effectiveness of the curriculum „ ? Provides information about continuous quality improvement

28 1.4.3.-Approaches to Curriculum Issue Who determines curriculum? What does iknowledge look like? What are the underlying assumptions? What might this look like in action? How is learning assessed? Traditional Approach ? Curriculum developer (Publisher, state, institution) sets goals and chooses learning experiences, evaluates, plans and proceses curriculum ? Appears neutral and equitable in its availability ? Exists 'out there,' can be organized and transmitted ? Is observable and measurable ? Pre-determined goals ? Learning happens in a linear, step-by- step fashion ? Expert knowledge is important ? A classroom with lesson plans, homework, grades possibly Skills-based/ ? sequenced text- books or workbook with pre-determined learning goals ? Objective, observable 'scientific' means ? Can provide comparative scores Learner-Driven Approach ? Students articulate learning goals that spring from their real-world roles. ? Students help plan curriculum ? Created through the interaction of student and text ? Builds on what learners already know ? Relevant to students real-life context ? Learning happens in social contexts ? Instruction is transparent and based on purposes students determine ? Learners actively build on knowledge and experience ? A political on the surface ? Drawn from adults' lives in their everyday contexts ? Performance of the student's contextualized goal ? Continuing, involving metacognitive strategies Critical Approach ? Teacher leads the class white following the lead of learners ? Students, rather than 'outsiders', become experts ? Not fixed-dependent upon interaction among students, text, and teacher ? Autobiographic-depends on the politics of identity brought to learning ? Complex interaction between text, the teacher, and what is taught ? knowledge is created, rather than taken in ? Education is political ? Language and power are connected ? Abandons technician mentality ? Addresses social and community issues of importance ? Curriculum not set in advance : emerges from action and interaction of the participants (Doll, 1993) ? Portfolios, self-assessment instruments Measures of social and personal change ? Levels of critical consciousness reached ? External performance levels do not apply

29 1.4.4- Curriculum adaptation in for the Children with Hearing Impaired

Curricular adaptations are mostly suggested for hearing impaired children who need non audio experience in adaptation of learning materials for the use of children with hearing disabilities.

The teacher of the hearing impaired had to make special and planned efforts to provide opportunities in following the criteria repeatedly. 1. Listening with understanding especially in auditory training. 2.

Interpreting the written symbol with picture (Stage by stage it has to be developing based standard). 3. Try to develop their reasoning capacity through experience. 4. To provide realistic experience for concept building. 5. Give opportunities for their expressive language (communicating by speaking or by writing). 6. Try to teach the concept in an enjoyable and interesting manner. 7. Need sustained efforts for a long period of time to get response, because the results will not be seen immediately. 8. Simply the actual lesson into small, small task and directed activity based. 9. Find out the meaning for the complex word in the particular lesson. 10. Try to avoid the complex sentence while speaking and writing. 11. Try to avoid the different meaning for same word. 12. Teach the task with appropriate aid. 13. To use visual aids as much as possible. 14. To avoid more speaking during taking class. 15. Speak clearly with correct pronunciation with appropriate sound level. 16. Don't insist in completing the task without comprehension.

30 1.4.5-

Curriculum design for Children with Hearing Impaired Children The main issue of Curriculum design for Children with Hearing Impaired Children is academic issues Academic issues Most of the hearing impaired students will suffer from low self-esteem or a greater than normal worry about their ability to cope with higher education. So you can monitor how well you are meeting their needs. Not all hearing impaired students have the same degree of hearing impairment or loss, nor have they the same technical and personal coping strategies. Some were born hearing impaired while others became hearing impaired after they had learned to speak. This will affect how they communicate with the hearing world. Avoid stereotyping hearing impaired students; explore the needs of each individual, undergraduate or postgraduate, full time or part time. For hearing impaired students who rely on signing, British Sign Language is their first language and English is their second. To them, English is a foreign language with a very different structure and grammar as well as vocabulary. The sign languages used in other countries are not mutually comprehensible with BSL; they are different languages in their own right. Sign Supported English is a half way house – English supported by some signs from BSL. A few hearing impaired students will find the use of English, written or spoken, very difficult. Some people, profoundly deaf from birth, may speak in a way that is difficult for hearing people to understand, though you can quickly 'tune in'. Some hearing impaired students may need an interpreter to translate their signing into spoken English, though there is a shortage of these highly skilled people. The interpreter translates what the tutor says into BSL; and the student's questions, expressed in BSL, are translated into English for the tutor to respond to. The possibilities opened up by speech recognition software could be very helpful for hearing impaired students since it has the potential to produce an accurate, real-time, accurately digital record on a laptop of all that was said in class. However, the reliability of such software is not yet as high as one would wish, especially when there are several speakers with different accents and articulation recorded in far from ideal conditions. Digital

31 hearing aids can out-perform analogue ones by boosting the signal-to-noise ratio. The lecturer wears a radio microphone which transmits a signal to the radio receiver worn by the student. This can work well in a lecture where most of the talking is done by the lecturer. In a seminar a radio microphone could be passed around among the speakers, which helpfully limits who is speaking to one at a time. So there are many issues in related to academic issue. These are: a. Information and informed choices b. Course induction c. Room requirements d. Techniques e. Seminars and tutorials f. Practical g. Web-based learning h. Virtual learning environments a. Information and informed choices The most successful students are arguably the ones who start by making wise and well-informed choices amongst potential courses. Like all other students, those who are hearing impaired need full information on the content and assessment of modules so they can check courses' suitability and how they will fit with their career path. It is even more important for students with additional needs, such as d/Deafness, to make the best choice so that difficulties at a later stage are minimized. Of course, hearing impaired students' choices will also be affected by all the usual criteria students use, not just by issues of hearing. In order to make these choices students will need: ? Chances to meet admissions staff at open days.

32 ? Opportunities to discuss their individual needs with a tutor to sort out issues in advance. ? Details of the desired learning outcomes and the teaching and assessment methods they are likely to encounter on a course and details of the fieldwork in particularly in terms of communication. ? Information in advance, so it can be studied carefully. ? To know something about the learning environment and support facilities. ? Different routes to this information – textual in handbooks and on websites, visual, diagrammatic and photographic. ? Clarity of language is paramount since d/Deaf users of BSL may have English as their second language. ? Tried and tested methods of information presentation (test that your use of language is accessible to, say, a non-native speaker of English). ? Access to advice (in person with staff; to Frequently Asked Questions sections of web pages; to students who have done the course before; to reports of fieldwork activities and to photographic records). ? Information that is consistent between departmental and institutional material and between various support units. ? Assurance that a degree of flexibility is built into the design of the curriculum. b. Course induction Institutions and individual academics make many assumptions about student knowledge and experience. Yet many students may not be familiar or at ease with the conventions of higher education and spend considerable time learning about university norms. This will be particularly true of students from backgrounds where going to university is not the norm.

33 What exactly is a lecture? What do you do in a seminar? What does fieldwork at university entail? For d/Deaf and hearing impaired students it is much more difficult to get these cues since much is picked up through overheard remarks and chance comments – precisely what hearing impaired students have difficulty with. It therefore becomes the responsibility of the lecturer to find ways of helping hearing impaired students to access this information. A handbook and website will help – with some basic rules and principles of university education, and descriptions of the range of courses. It could also provide some informal reports of previous students' experiences. Do remember here the part-time students (undergraduate and postgraduate) who need the same levels of course information, induction and one-to-one discussion of needs and coping adjustments, but may not be as readily available for these to take place as the full-time students. Their needs must also be met. c. Room requirements Check the room where you will be lecturing to hearing impaired students. ? Has it got an induction loop for students with hearing aids? If not, could the lecture venue be altered to a room which does? ? Check the microphone is working correctly; remember to switch on the microphone and ensure the student is getting a clear signal. Try not to touch the microphone when in use. ? The room got power points for students with tape recorders or laptops (though from a health and safety viewpoint, batteries are preferable to avoid trailing wires). These power points near the centre of the room which is the optimal location for a student who wishes to lip-read the lecturer.

34 ? Is the room going to be overcrowded and is there background noise? Uses more microphone and several loudspeakers that will help the whole classes. ? Ensure lighting is adequate and correctly positioned for lip-readers and interpreters. d. Techniques: ? Be clear, well directed and follow a logical pattern so that the lecture is easy to follow, which will help all your students but particularly hearing impaired ones who will not be able to lip-read everything. ? It is impossible to lip-read (or watch an interpreter) and take notes at the same time. So it helps if you can provide information about the lecture and copies of the handouts and overheads in advance, before the lecture or on a website. ? Do not speak too quickly, shout or over-articulate (which distorts sound and lip patterns). ? Ensure your lips are visible and not covered with hands. ? Re-iterate key points, re-phrase information; a repeat question asked from the body of the class to make sure everybody hears the question. ? Don't move about the room; lecture to the students, so lip-readers can see your face. ? Resist the articulation to keep speaking when you turn away to write on the blackboard/whiteboard or read material from an OHP, slide or PowerPoint display. ? Turn off the OHP when not in use because the noise of the fan can affect hearing aids. ? If the lecture uses audio material (e.g. video or DVD or an audio recording), ensure you provide a transcript or that material is captioned or sub-titled. Tools for captioning computer-based video and multi-media material can be downloaded from.

35 ? If the lecture is long, remember that d/Deaf students find following a lecture very tire even with lip-reading. Their interpreter may also need breaks. ? Ensure that lecture notes and copies of OHPs or PowerPoint slides are available (as a handout or on a website) in advance of the lecture if possible, so the student can become aware of the material and its vocabulary. ? If students wish to tape-record lectures for later transcription, ensure they sit at the front and that there is a plug for their machine. Battery-powered machines are preferred to avoid the need for compact wires which can be a health and safety. e. Seminars and tutorials For the hearing impaired student, the main difference between a lecture and a seminar/ tutorial is the larger number of speakers, the more multidirectional nature of the teaching situation and the more varied the range of activities which can take place. Here are some practical things which can allow full participation in a seminar or tutorial. ? If possible, choose a room in a quiet location; reduce background noise and reducing echo. ? Think about the seating arrangements, e.g. put chairs into a semicircle so students who lip-read can see everyone's face. This is very difficult if the seminar is in a lecture theatre where the seating cannot be re-arranged. ? Allow only one individual to talk at a time. Only one person at a time can be lip-read and people to speak in sequence. Students could be asked to raise their hand before speaking, so the d/Deaf student knows where to look. ? Repeat or paraphrase the discussion. Tutors can often make student contributions clearer by summarizing comments on a flipchart or board. . ? Provide a briefing paper before the tutorial. This lets students prepare for the discussion and potentially increases their confidence. Prior notice of the topic and

36 main ideas provides the context for successful lip-reading and students who use an interpreter will need notice of any new terms. ? Have breaks if the tutorial is particularly long so students remain active participants. Lip-reading is tiring and if a BSL interpreter is used, s/he should have a break every hour. If an interpreter is needed for more than half a day, two should be employed in turns. ? For students with hearing aids, the use of a radio microphone will assist them in participating fully in the tutorial, particularly if there is external noise. However, if talking individually to other students, remember to switch off the microphone, otherwise your voice will be sent needlessly to the d/Deaf ones. ? Give hearing students time to relax and feel confident enough to speak in a group situation. ? Ensure guest speakers are informed about the needs of hearing impaired students in a tutorial or seminar. ? In some seminars or tutorials, students may have to give an oral presentation, and this can be a source of considerable anxiety. Hearing impaired students may be anxious about group participation or carrying out a presentation. They may be sensitive about how their voice sounds. Be sensitive and encourage the student to be honest about any issues, so that there is room for discussion and resolution of the problem. Discuss the use of an interpreter to translate the hearing impaired student's BSL. f. Practical Here are some useful ideas for effective practical classes with hearing impaired students. ? Use written information for any instructions and captions or a transcript if video material is used.

37 ? Distribute in advance a printed outline of the laboratory tasks so the student is prepared and can discuss with you any problems they think they may face. ? Provide an individual orientation to the laboratory including equipment and health and safety procedures. ? Always discuss procedures and any special safety issues before the experiment begins. ? Arrange and discuss evacuation plans for fire and other emergencies and ensure visual fire alarms. ? Alarm systems should be visual with flashing lights. In practice, expensive changes to equipment are seldom needed for deaf students. For example, they can feel a timer ringing if they hold it. ? Ensure that the hearing impaired students working partner is happy to be the ears for both of them but does not take over all the work. ? Text messages by mobile phone can be used for prompts or brief safety reminders. g. Web-based learning In general the web provides a very effective learning medium for the hearing impaired student because it is so visual. However, one area to watch is training in the use of the web. This will need to focus on instructions and support which can be read. It is impossible to lip-read a web trainer, operate a keyboard and mouse, and look at a PC screen all at the same time. Occasionally a website will have an audio clip or even audio streaming of say a speech, interview or radio station. This purely aural material will need interpreting for the hearing impaired student using a BSL signer or a note-taker or through a summary prepared by the tutor if possible provided in advance.

38 h. Virtual learning environments A Virtual Learning Environment (VLE) can be configured in various features. These are websites, email, video-conferencing and telephone support to tutors along with paper-based learning materials. The elements of a VLE create no particular problems for hearing impaired students specially the paper-based materials, emails and websites. So, hearing impaired student before they start within a VLE and talk through how they can use this style of delivery most effectively. 1.5-

Curricular Needs of children with hearing impairment in Scholastic Areas 1.5.1-Curricular Needs of Scholastic Areas

Education completes man. Students need quality education suitable for life. Perceiving the needs of the learners, appropriate changes are made in the curriculum, syllabus and textbook on a need basis. Currently changes have taken place in the evaluation system. The long-practised marking scheme has been done away with and grading system has been brought in its place. The students are assessed not only during examinations but all through the term. Evaluation is conducted through activities,

observation and group discussion. The evaluation is done under two parts namely scholastic and co-scholastic activities. Scholastic activities have been further classified into two parts viz. Formative and Summative Assessments. Students get knowledge of the subjects through scholastic activities. They get knowledge of the society. The scholastic area and achievement of students with hearing loss is one of the most important determinants of recipient's quality of life in schooling system. The scholastic achievement of students with hearing loss attending the mainstream schools and to compare their scholastic performance to their normal hearing peers. So scholastic performance in mainstream schools is a most important factor because it is all round development of the children with hearing impairment is the dynamic trend in the new educational system. The school has now emerged as a place where students acquire

39 various skills. Effective schools follow a holistic approach to education i.e. an integrated development stressing on physical, mental, moral and social aspects. A lot of innovations are going on in the field of education. It has become child "centred". A teacher inspires a child to know things himself through constructive activities. The main function of the teacher is to help children develop their talents, abilities and capabilities. This education system encourages a child to acquire more knowledge. A holistic approach to education at the elementary level is a must as it is the most important subsection of the whole education system. Such an approach will facilitate the total development of a child by providing the right atmosphere for learners to develop and enrich their talent. Building self- concept, self image, sense of enterprise and sportsmanship and so on should be part of the educational process. Therefore the curriculum is designed giving due emphasis on both scholastic and co-scholastic area.

1.5.2- Aims of Scholastic Activities ? Producing a generation of students who interact with their environment effectively. ? Developing the collective spirit and overcoming egoism. ? Developing desired behaviours, e.g., self-reliance, initiative, innovation, creativity, observation. ? Developing the ability to make informed decisions and the sense of responsibility. ? Training the students on political affairs, e.g., applying for student boards, participating in election and self-judgment. ? Getting used to planning for and implementing group work. ? Enjoying oneself through the gratification and the development of skills, interests and inclinations. ? Professional guidance and respect for manual work.

40 ? Participating in some aspects of school administration and solving some student and administrative. ? Positive citizenship.

1.5.3-The Importance of Scholastic Activities There are many important scholastic activities for children with hearing impairment. These are: ? Providing the students with the experience and skills that are necessary ? Enhancing the students' talents and abilities. ? Inculcating the collective spirit in the students and training them on collaborative work. ? Training the students on overcoming the problems by own self. ? Education the students with the ability to cope and respond to others.

1.5.4-Functions of Scholastic Activities: There are many functions of Scholastic Activities in children with hearing impairment. These are Psychological, Social, Educational, Achievement, Recreational, Remedial and Economical. Psychological: ? Activities develop to talents and the ability to adapt. ? Constitute a motive for learning self-confidence. Social: ? Activities help the students to establish intimate relationships with others and inculcate in them responsibility, cooperation respect for others opinions.

41 ? Activities involve work, which develops in them social skills and values. These skills and values are developed in the involve in the group work where they collaboratively and enthusiastically plan, set of goals. Educational: ? Provide concrete and direct experiences and entail interaction with the components which helps with the learning of knowledge and skills and the gratification of the motive to do new idea. ? Strengthen the motive to learn and enhance the students' scholastic achievement and encourage active role in learning, allow for personal experience and help the students to learn many skills. ? Help the students to discover and promote their abilities and to make possible self- learning, life-long learning and problem solving idea. Achievement: Scholastic activities concern with the educational experiences included education in order to help the students to develop the different dimensions of personality. Recreational: This function is represented in art programs, school trips, games, celebration and competitions and other co-curricular activities.

Remedial Scholastic activities help with the remedy of many psychological disorders such as introversion, disorders, etc.

42 Economical This function is represented in the students' making use of time in doing something useful, encouraging work and raising the level of performance.

1.5.5-Guidelines for addressing children with hearing impairment concerns while developing curriculum: When every child in the classroom including children with special needs are provided with an opportunity to learn maximum according to their learning potential, to make required adaptation in regular curriculum (learning content, learning approach, learning aids and evaluation), to apply all possible approaches, it is known as Curriculum adaptation. Curriculum adaptation is not a separate method for children with disabilities. It is a process of making necessary changes in learning content such as modification, substitution/ replacement, omission as a last resort and compensation etc. without changing the learning purpose. Keeping the children with disabilities in mind while adapting the curriculum, small changes in learning content, learning friendly environment, appropriate learning approach, adaptation in learning aid and

evaluation should be done. If the curriculum is planned in this way and applied like this for all children in the classrooms, then learning can be maximized for all children, including children with disabilities. While planning curriculum, attention must be given to the needs of any child with disability. Here learning purpose may be the same for all students, but the learning experiences may vary from child to child. The following guidelines must be kept in mind while developing an inclusive curriculum for all children.

The curriculum must:

- Include child centred pedagogy keeping in mind the child's psychological development, interests and specific learning needs
- Ensure equal access in every possible manner (physical, attitudinal, academic and social) to maximize learning

43 •

Facilitate learning in an inclusive learning environment with accessible material, positive attitude and relevant/adaptive teaching strategies •

Incorporate required adaptation in curriculum (learning content, learning approach, learning aids and evaluation) to address and accommodate individualised learning styles, •

Prescribe for use of all available educational / assistive technologies to ensure equal participation of and effective learning in all children specifically for children with special needs • Include all children with and without special needs by providing differential opportunities to demonstrate learnt skills according to their learning abilities, •

Include components of life skills through transitional stages working towards independent living • Include locally available conditions/ opportunities/ situations to develop pre-vocational and vocational competencies • Integrate work pedagogy in education and include broad-based work experiences taking care of the needs of children with special needs • Ensure participation of children with special needs

in play, games, social and cultural activities to improve the physical and mental health by developing appropriate adaptations • Provide flexibility in school and class time tables to address individual needs of children • Create opportunities for facilitated social interaction • Construct knowledge by connecting new ideas to existing ideas on the basis of materials/ activities.

44 1.5.7-

Curricular Inputs children with hearing impairment in Scholastic Areas Education Evaluation is the of characterizing and appraising some aspect/s of an educational process. There are two common purposes in evaluation which are, at times, in conflict with one another. Educational institutions usually require evaluation data to demonstrate effectiveness to funders and other stakeholders and to provide a measure of performance for marketing purposes. Educational evaluation is also a professional activity that individual educators need to undertake if they intend to continuously review and enhance the learning they are SL NO 1 2 3 4 5 6 7 Key learning areas within the curriculum guidelines for special educational needs Communication and language Mathematics (including mathematical activities) Social, environmental and scientific geography, science (understanding and relating to the environment) Social, personal and health education Physical education (including functional movement) Arts education (visual arts, music, drama) Religious and moral education Curricular areas in Schools Language Mathematics Social, environmental, scientific education, history, geography science Social, personal and health education. Scholastic key issues of learning areas

45 endeavouring to facilitate. The evolution are Formative Evaluation and Summative Evaluation ? Formative Evaluation: This evaluation accumulates information to enhance methods and optimize education while the education is in progress. ? Summative Evaluation: This final, total evaluation, which takes place after fixing and repairing by Formative Evaluation, gives a diversified decision about a completed education process or the total result or effectiveness of programme. Assessment in education is the process of gathering, interpreting, recording, and using information about pupils' responses to an educational task. (Harlen, Gipps, Broadfoot, Nuttal, 1992). In Curricular Inputs children with hearing impairment in Scholastic Areas assessment is two types. These are: ? Areas of assessment ? Dimensions Areas of assessment The assessment is based on Revised Bloom's Taxonomy's on educational objective. The figure below depicts the tradition Bloom's Taxonomy's and Revised Bloom's Taxonomy's.

46 Dimensions There are five steps of dimensions of Scholastic activities. These are: ? The cultural dimension ? The social dimension ? The artistic dimension ? The Scientific Dimension ? The Sporting Dimension ? The Cultural Dimension: This dimension includes the programs of the groups whose activities development of knowledge, experience, awareness, and literary production in an organized framework. These groups are the group of the school Change in Terms

The names of six major categories were changed from noun to verb forms. As the taxonomy reflects different forms of thinking and thinking is an active process verbs were used rather than nouns. The subcategories of the six major categories were also replaced by verbs and some subcategories were reorganised. The knowledge category was renamed. Knowledge is an outcome or product of thinking not a form of thinking per se. Consequently, the word knowledge was inappropriate to describe a category of thinking and was replaced with the word remembering instead. Comprehension and synthesis were retitled to understanding and creating respectively, in order to better reflect the nature of the thinking defined in each category.

<http://rite.ed.qut.edu.au/oz-teachernet/training/bloom.html>

47 press, the group of the library, the group of the activities language (handwriting, verse writing, story writing, reading poetry, acting and school broadcasting and religious activities. ? The Social Dimension: This dimension includes the programs of the groups whose activities development of social skills, values and attitudes. Examples of these groups are the group of the people, the group of school trips, the group of cooperation, the group of school exhibitions etc. ? The Artistic Dimension: This dimension includes the programs of the groups whose activities to practice activities like playing music, singing and drawing. It includes the groups of music, drawing, products and theatrical work. ? The Scientific Dimension: It includes the programs of the groups whose activities address research. An example of these groups are the science club (this includes various groups) the agriculture scientific projects group, the research group, and audio-visual presentations group. ? The Sporting Dimension: This encompasses the groups whose activities address physical skills. Like are ball teams (football, basketball and handball), swimming teams and scouts. All types of activities serve the same purposes. Besides, the same fulfilled through more than one activity type. A theatrical performance, for instance, can involve acting group, the electricity group, etc. That the group and the practice of the various groups are meaning that the aim is different. All the activities interact whether in aims and/or practices. Categorization only for the purposes of planning, implementation, follow-up and organization. An activity achieves the desired aim if given positive elements are secured. These elements or components the group, the activity supervisor and the organization of the group work: 1.5.8- Basic criteria of scholastic areas in children with hearing impairment: 1.

Cognitive validity requires that the content, process, language and pedagogical practices of the curriculum are age appropriate, and within the cognitive reach of the child.

48 2. Content validity requires that the curriculum must convey significant and correct scientific information.

Simplification of content, which

is necessary for adapting

the curriculum to the cognitive level of the learner, must not be so trivialised as to convey something basically flawed and/or meaningless. 3. Process validity requires that the curriculum should engage the learner in acquiring the methods and processes that lead to

the

generation and validation of scientific knowledge and nurture the natural curiosity and creativity of the child. Process validity is an important criterion since it helps the student in 'learning to learn' science. 4. Historical validity requires that the

science curriculum be informed by a historical perspective, enabling the learner to appreciate how the concepts of science evolve over time. It also helps the learner to view science as a social enterprise and to understand how social factors influence the development of science. 5. Environmental validity requires that science be placed in the wider context of the learner's environment, local and global, enabling him/her to appreciate the issues at the interface of science, technology and society, and equipping him/her with the requisite knowledge and skills to enter the world of work. 6. Ethical validity requires that the curriculum promote the values of honesty, objectivity,

cooperation, and freedom from fear and prejudice, and inculcate

in the learner a concern for life and preservation of

the environment. 1.5.9- Scholastic achievement of students with Hearing Loss. ? Language and speech- The ability to learn language and speech is the highest development of children with hearing impaired. ? Intellectual ability- Process of thinking of deaf children and normal peers are found to be similar also cognitive abilities and develop verbal intelligence.

49 ?

Academic Performance- Hearing impaired children are frequently handicapped in various degree of hearing loss and it affects

educational

performance and particularly reading which relies heavily upon language skill. So

after scholastic achievement hearing loss student can develop the academic performance. ? Adjustment of social- Our social inter action depends upon communications. So deaf children have communication problems. That's why it should have problem of social inter action. Such children live in a world of isolation and form a group of their own, an association of the deaf for their common interest and interaction. So

after scholastic achievement student with hearing loss can develop on adjustment in

social inter-action. ? Behavioral problem- Deaf learners feel invariably inferior and helpless in adapting to circumstances that require verbal communication. So regard non-verbal communication absence of verbal they have poor self poor concept which damages the development of personality but with the help of mainstream education which is scholastic achievement they develop the personality and reduced

the problem behaviour is reduce regard various social academic aspect. ? Socially handicapped – Learners with hearing loss cannot adjust with society because they suffer from communication difficulty and fail to understand what normal people say. But after scholastic achievement with the help of mainstream they develop communication skill and mixing the oral social

which is social of communication and reduced of socially

handicapped. ? Problem in personal and social development- Language becomes a barrier for deaf learner for purpose of communication with others. So this affects the socialization process and plays a vital role in the personal and social development of hearing loss learner. So with the help of scholastic achievement in mainstream in regular class room it develops the normal peer acceptance and reduces the problem in personal.

50 ? Personality problem- Hearing difficulty may create personality problem. A deaf learner becomes more frustrated as he/she tries to reach the level of the normal. Hence a totally deaf child seems reconciled to his fate, but given well provided adequate facility of language and communication regard literacy development in regular school they develop personal adjustment and well developed scholastic achievement in hearing impaired students. ?

Provided in natural and social environment- For a child with hearing loss to scholastic achieve developmental synchrony even development across the developmental domains programs need to provide a richer, more natural social environment and consistent exposure

to hearing peers who can model age- appropriate language and social development. ?

Mainstream Placement-

Another choice commonly made for children with hearing loss is mainstream placement. The term mainstreaming is used to refer to the placement of regular education classes based on their skill level. Mainstream education does seek to educate the "whole child" and provide exposure to many preschool programmes. However, many schools turn to more directive teaching models by kindergarten wherein children sit at desks, teachers instruct, and children acquire facts, skills, and concepts through drill and practice. 1.6

Curricular Needs of children with hearing impairment in Non- Scholastic Areas

A Child's holistic development is not measured only by his/her

academic achievements. Sports & Games, Arts & Fine Arts and social skills combined together with intellectual excellence makes a student what he or she will be when he blossoms into an adult. In view of this, opens an avenue of Non-Scholastic activities to prepare children with hearing

51 impairment for his greater journey of life. Non-scholastic abilities are not just 'nice to have' or 'desirable to have', but 'must have' qualities.

Non-scholastic activities

like Yoga, Music, Dance, Sports and other activities moulds the wholesome personality in students and implemented for character development in students. 1.6.1-

Meaning- The non-scholastic abilities are concerned with the learner's attitudes, interests, values, feelings, habits, social interaction which cannot be accessed directly. It is assessed indirectly by merely observing the behaviour of the learner and his experiences and also through biographies, self-reports and checklists etc. The

non-scholastic aspects of children with hearing impairment techniques have been Subjective Methods, Objective Methods and Projective Techniques 1.6.2- Relevant Areas of Non-Scholastic Assessment Some of the relevant areas of non-scholastic assessment are: 1.6.2.1- Health and Physical education – ? It is widely acknowledged that health is influenced by biological, social, economic, cultural and political forces. Access to basic needs like food, safe drinking water supply, housing, sanitation and health services influences the health status of a population, and these are reflected through mortality and nutritional indicators.

52 ? Health is a critical input for the overall development of the child and it influences enrolment, retention and school completion rates significantly. This curriculum area adopts a holistic definition of health within which physical education and yoga contribute to the physical, social, emotional and mental development of a child. Therefore, the need to address this aspect at all levels of schooling, with special attention to vulnerable social groups. ? The more recent addition to the curriculum is yoga. The entire group must be taken together as a comprehensive health and physical education curriculum, replacing the fragmentary approach current in schools today. As a core part of the curriculum, time allocated for games and for yoga must not be reduced or taken away under any circumstances. ? There is growing realisation that the health needs of adolescents, particularly their reproductive and sexual health needs, require to be addressed. Since these needs predominantly relate to sex and sexuality, which is culturally a very sensitive area, they are deprived of opportunities to get the appropriate information. As such, their understanding of reproductive and sexual health and their behaviour in this regard are guided predominantly by myths and misconceptions, making them vulnerable to risky situations, such as drug/ substance abuse and HIV/ AIDS transmission. Age- appropriate context- specific interventions focused on adolescent reproductive and sexual health concerns, including HIV/AIDS and drug/ substance abuse, therefore, are needed to provide children opportunities to construct knowledge and acquire life skills, so that they cope with concerns related to the process of growing up. 1.6.2.2- Attitude & Values: ? Respects school property ? A ware of / sensitive to the threats posed to nature by mankind, shows responsibility towards the environment, is environmentally sensitive

53 ? Participates in school driven activities relating to care for the environment ? Participates in community driven activities relating to care for the environment ? Takes the initiative and plans activities directed towards the betterment of the environment ? Cares for others, respect life, respect Mother Earth, love for one's own country. ? Understands the need for rules and follows them. ? Has Self – respect ? Exhibits leadership ? Respects diversity (culture, opinions, beliefs, abilities), respects the opposite sex ? Shows a kind, helpful and responsible behaviour/attitude. ? Displays commitment and an open mind works efficiently, respects time, his/ her own and others' ? Displays a positive attitude towards peers, adults and community; seeks and provides solutions. ? Peace loving; Strives for conflict management in all stressful situations. ? Ability to find happiness within oneself 1.6.2.3-Psychological Issue: ?

Desirable interests, personality traits including motivation, concentration, independence, initiative, self-discipline, self-esteem, responsibility, drive, leadership. ?

Analytical thinking, critical-thinking, lateral thinking and problem solving are required in most occupations on the needs based. 1.6.2.4-Emotional Issue: ? Development of emotional maturity with balance and integration. ? Identify one's own strengths and weaknesses.

54 ? Be comfortable with one's own self and overcome weaknesses for positive self-concept. ? Identify causes and effects of stress on oneself. ? Develop and use multi-faceted strategies to deal with stress ? Ability to express and respond to emotions with an awareness of the consequences. 1.6.2.5-Life skills Life Skills are

abilities for adaptive and positive behaviour that enable individuals to deal effectively with the demands and challenges of everyday life. They

are abilities that facilitate the physical, mental and emotional well-being of individuals (WHO) ? Thinking Skills These include decision-making, problem-solving skills and information gathering skills. The individual must also be skilled at evaluating the future consequences of their present actions on others. They need to be able to determine alternative solutions and to analyze the influence of their own values and the values of those around them. ? Social Skills These include verbal and non-verbal communication, active listening, and the ability to express feelings and give feedback. Also in this category are negotiation/refusal skills and assertiveness skills that directly affect one's ability to manage conflict. Empathy,

55 which is the ability to listen and understand other's needs, is also a key interpersonal skill. Team work and the ability to cooperate include expressing respect for those around us. Ø Emotional Skills These refer to skills which help one to increase the internal locus of control, so that the individual believes that she/he can affect change and make a difference in the world. 1.6.2.6. -Literacy/Reading Skills Issue. The development of literacy and reading skills hearing impairment children is not a multifaceted issue. It is possible to find a good number of parallels to literacy development in their hearing peers. Current millennium still reports that children with hearing loss are often severely delayed when compared to hearing children, especially in earlier development. Adolescents with hearing loss are still seen to have multifaceted problems involving literacy (reading and writing) and language that can influence their attitude to their ability to access and use academic information. This also has implications for how they regard academic information and whether they are willing to apply it. If adolescents with hearing loss are able to access and use academic information sufficiently, they will be able to fulfil a more significant role in society, as well as to study and work well. The acquisition of academic information will enable adolescents with hearing loss to function in such a way that they will be able to maintain their independence and improve their knowledge base throughout their education years. According to Briggie (2005) some class activities that are beneficial to hearing impaired or deaf children includes: 1)

Time to explore writing, drawing, books and environmental print 2) Story time translated in to sign 3) Journal writing using invented spelling.

56 Like hearing peers hearing impaired or deaf children should have the opportunity to participate in literacy events. They should also use written language in many ways that are typical to their hearing peers. According to Briggie (2005) and Williams (1994) the teacher should provide them with the opportunity of demonstrating the following uses of languages in

signed or spoken from: 1) To interact socially with peers and adults while writing. 2) To provide information about written text. 3) To label written creations. 4) To monitor the construction of text. 5) To request assistance with writing tasks from adults and peers, 6) To challenge others' knowledge of literacy, and 7) To evaluate literary works. 1.6.3-

Curricular guidelines of children with hearing impairment in Non-Scholastic Areas The Curricular guidelines develop for students with mild, moderate and severe and profound hearing disabilities will be flexible enough to be accessed by a broad variety of school and class types. They will allow for choice and have a practical life-skills orientation that addresses both the present and the future needs of the student. They will also address assessment issues with a view to providing an accurate record of the student's cognitive and attitudinal strengths and to identifying clearly opportunities for future learning. The curriculum guidelines will incorporate the development of key skills within broad content areas and it is a continuum of curricular provision that recognises and addresses students' appropriate levels of achievement and takes due account of needs, ability and age- appropriateness. The guidelines will be adaptable for use in different circumstances and be capable of extension and refinement.

57 Steps in assess in

non-scholastic areas ? Identification of qualities to be assessed. ? Specification of the behavioural indicators ? Collection of the evidence to support behaviour through observation and other methods ? Recording of the behaviour ? Analysis of the behaviour ? Reporting or Grading ?

Broad principles and aims of education for students with general learning disabilities ? The identification of realistic, time-referenced targets ? The use of individualised education programmes ? The use of a variety of assessment tools ? Lines of development in the skills areas, with short exemplars illustrating how they can be developed ? New content and linkage points to national curricula at both primary and post- primary levels where appropriate ? Whole-school and classroom planning approaches that will facilitate schools and teachers in developing and implementing an appropriate education policy for students with special educational needs ? A range of multi-disciplinary approaches in the education of students with special educational needs.

58 Fig: Block diagram in Curricular Guidelines

Needs of children with hearing impairment in Non-Scholastic Areas 1.6.4-

Types of Non-Scholastic

Areas. These are nine types curricular adaptation in children with hearing impairment in Non- Scholastic Areas. These are: ?

Quantity ? Time

59 ? Level of Support ? Input ? Difficulty ? Output ? Participation ? Alternate Goals ? Substitute Curriculum

Sl. No. Types Non-Scholastic Areas 1.

Quantity

Adapt

the number of items that the learner is expected to learn or complete. For example: Reduce the number of social studies terms a learner must learn at any one time. 2.

Time Adapt the time allotted and allowed for learning, task completion, or testing. For example: Individualize a timeline for completing a task;

pace learning differently (increase or decrease) for some learners. 3.

Level of Support Increase the amount of personal assistance

with

a

specific learner.

For example: Assign peer buddies, teaching assistants, peer tutors, or cross age tutors. 4.

Input Adapt

the

way instruction is delivered to the learner. For example:

Use different visual aids,

enlarge text, plan

more concrete examples, provide hands-on activities, place students in cooperative groups.

60 5.

Difficulty Adapt the

skill level, problem type, or the rules on how the learner may approach the work. For example: Allow the use of a calculator to figure math problems; simplify task directions; change rules to accommodate

learner needs. 6. Output Adapt how the student can respond to instruction. For example: Instead of answering questions in writing, allow a verbal response, use a communication book for some students, allow students to show knowledge with hands on materials. 7.

Participation Adapt

the extent to which a learner is actively involved in the task. For example: In geography, have a student hold the globe, while others point out locations. 8.

Alternate

Goals

Adapt

the goals or outcome expectations while using the same materials.

For example: In social studies, expect

a

student to be able to locate just the states while others learn to locate capitals as well. 9. Substitute Curriculum Provide different instruction and materials to meet a learner's individual goals.

For example: During a

language test one student is learning computer skills in the computer lab. 1.6.5-Assesment Issue There are many issues of Non-Scholastic Assessment in hearing impairment. These are: ? Assessment of Communication and Interpersonal skills ? Cultural Competence Training and Assessment ? Assessing written communication skills

61 ? Assessment of oral communication skills 1.6.5.1-Assessment of Communication and Interpersonal skills Assessments of Communication and Interpersonal skills are ? Auditory Abilities and Skills ? Communication Evaluation ? Areas of Psycho-educational Evaluation ? Auditory Abilities and Skills: Auditory Abilities and Skills information will help guide appropriate planning for educational and classroom accommodations to promote auditory access to the curriculum. An assessment should provide necessary information regarding the nature and degree of hearing, the child's auditory perception skills and abilities, use and benefit from amplification and assistive technology, and specifics related to their auditory and listening performance in the typical classroom. To ensure appropriate expectations, consider the overall needs of the student with respect to chronological age, age of full-time device use, and language and academic skills expected of their same aged peers. Testing should be completed under ideal listening conditions as well as under simulated classroom conditions, and may include traditional sound booth testing, classroom observation, and input from the student's instructors. ? Communication Evaluation A communication evaluation includes signed, spoken, and/or written language, as deemed appropriate for the individual. This evaluation includes the testing and gathering of information in the following areas: a. Phonological educational evaluation: voice, manner, placement, syllabication and reception of speech sounds b. Prosodic features: intonation, pitch, rhythm, and stress c. Voice quality, including nasality 62 d. Intelligibility of connected speech e. Semantic and grammatical accuracy f. Pragmatics/discourse g. Self-advocacy and independence with communication h. Cognitive academic language proficiency (CALP) i. Thinking and reasoning skills ? Areas of Psycho-educational Evaluation A psychological evaluation includes the testing and interpretation of human development and learning domains (i.e., cognitive, achievement, adaptive behaviour, emotional, social, behaviour, language, and perceptual-motor) within a collaborative, databased frame, respecting diversity of student strengths, needs, learning styles and cultures. Standardized evaluations may provide information regarding the student's skills and abilities in comparison with that of hearing peers. It is important to consider the evaluation results in conjunction with other evaluation information (e.g., criterion-referenced educational evaluation, portfolio educational evaluation, etc.) when developing the individualized education program. In addition to taking part in academic achievement testing for initial and additional evaluations, deaf and hard of hearing students should participate in the age-appropriate state wide and local educational evaluation programs unless they qualify for alternative forms of testing as determined by established criteria. The criteria are: a. Early identification: Early identification is important areas evaluated in visual discrimination, visual memory, visual-motor integration, visual figure- ground, visual closure, and spatial relations in related in auditory behaviour. b. Pre-Academic Skills: Pre-Academic Skills, or a developmental evaluation of readiness skills (e.g., visual discrimination skills, identification of letters and numbers, identification of body parts, matching, predicting, sorting, and basic concepts) is important for developing IEP goals and objectives and for determining when the child is able to acquire age-appropriate standards leading to academic instruction.

63 c. Achievement: Achievement or an evaluation of academic skills should provide information regarding the student's present level of functioning. This may include formal, standardized evaluations of student's skills as well as a review of academic progress in their current program and documentation of previous assessment data as pertinent to the current referral. d. Adaptive behaviour: Adaptive behaviour may be used for deaf or hard of hearing children for initial eligibility referrals as well as for those who are very young or who have multiple disabilities. Areas evaluated may include self-help skills, daily living skills, independent functioning, and communication and social skills. e. Social-emotional maturity: Social-emotional maturity should be a major component of the educational evaluation process for a deaf or hard of hearing student. Communication problems that result from lack of access to meaningful language contribute toward the development of personality and social/emotional adjustment. Emotional factors have a direct influence on the learning behavior. Social-emotional evaluations examine self-image, social/interpersonal skills, emotional adjustment, and life-style expectations. 1.6.5.2-Cultural Competence Training and Assessment Culture is a set of shared values, practices, conventions and attitudes. Culture is learned through interaction and strengthened as individuals with shared experiences connect and further refine their values, practices, conventions, and attitudes. Traditionally, culture is learned from parents. However, deaf persons are typically born to hearing parents unknowledgeable of deaf culture. Most parents do not know Sign Language or learn to communicate with their children and a language delay develops. The deaf child may not be able to socialize and develop friendships. A lack of communication is a common shared experience for deaf individuals. This communication void and inability to communicate with the world is the first of many cultural experiences demonstrating that the individual is different and belongs to the deaf culture. As deaf individuals become exposed to sign language and other deaf persons, the enculturation process becomes complete, and deaf persons identify themselves as ethnically deaf. Ethnicity is a product of situational and strategic adaptive processes, which develop identity boundaries and cultural content and context.

64 Belonging to an ethnic group is a rational decision. It is not a matter of shared genetics or ancestry. Instead, ethnic groups share commonality. The ethnically deaf have similar physical abilities, customs, and shared experiences. Discrimination for inability and resistance to assimilate fully into the greater hearing culture creates a "sense of Peoplehood" among the deaf and defines their shared ethnicity. 1.6.5.3-Assessing written communication skills (1) To provide ample opportunity to the child to write his/her own thought. (2) Link development of writing with reading, listening – speaking (or signing), context and experiences. Teachers always want to make tasks simpler for students

and

simplest way to make tasks simpler is to link it with meaning and context. Teaching writing for that matter, teaching anything without context or pragmatic background cannot

be good results in the long run. (3) In order to facilitate learning use of feedback is an essential factor. This in turn needs to be responded with feedback comprising: ? Clear ? In detail ? Indicative of higher expectation ? Appropriate ? Immediate ? In writing ? Consistent ? Objective ? Pro-active (4)

Writing should be

enjoyable and communication oriented rather than task-oriented. (5) Develop the habit of self-editing. Many times, looking at the writings of the children one can hardly know his / her current level of language competency. The teacher is

65 confused about whether an error committed by the student is an error of accident or is an outcome of incorrect knowledge of language. If the children are made to edit their own writing, correcting their inner language structures becomes possible. Initially teachers can mark the sentences, parts where modification is required. This can work as a clue to help him/her edit the overall write up. (6)

Carry out assessment of writing. Separate writing assessment needs to be carried out by the teachers on regular basis. Assessment of language or assessment of language text book cannot be considered as writing assessment. There is a difference between assessment of language through writing and assessment of writing. Like any other ideal assessment, writing assessment too has to be carried out systematically, consistently and objectively. (7) Involve parents in the process of writing development. As said earlier, writing needs to be developed in connection with context and real life situations. Home environment is rich from this point of view. Providing training to parents on follow up activities on development of writing is highly recommended. 1.6.5.4-

Assessment of oral communication skills According to Joughin and Collom (2003) there are six particular assessments of oral communication skills based on of educational practices. These are: I. Primary Content Type This refers to the particular skill or ability that is under scrutiny. Examples of such include the ability to demonstrate knowledge, communicate coherently and apply interview techniques. II. Interaction Whereas in some cases the student must compile and deliver a presentation and follow a rigid set of instructions with little or no interaction with the audience, in other instances the student is required to maintain a dialogue with his/her assessor/ s. In the latter, assessors may probe into and challenge the knowledge attained by their students, thus testing the scope of their knowledge.

66 III. Authenticity The authenticity of oral assessment is dependent on the context in which the assessment or presentation is taking place. Joughin (1998) describes the way in which in certain instances presentations are required to be carried out in the field of work that the students are aiming to find themselves in once qualified. On the other hand, Joughin (1998) describes reflects the lack of authenticity of the assessment, in that it is carried out "remote from the situation of professional practice," (Joughin, 1998:372), often in the classroom. IV. Structure The structure of the oral assessment refers to the way in which the presentation isorganised. While the 'closed structure' approach is defined by a present list of questions which are applicable to all students, the 'open structure' illustrates a loose flow of dialogue, questions and answers. In the latter, the assessor shapes their questions in accordance to the student's findings and the issues they raise or cover. V. Examiners Joughin (1998) compares the assessment of written work to that of oral presentations, stating that in the latter there is greater opportunity for alternative methods of assessment and evaluation. While in written assessment generally one or two assessors scrutinise the work of students and agree the overall grade, orally assessed presentations may more easily be viewed and critiqued by peers, by the students themselves, as well as by "teachers or others in a position of authority" (Joughin 1998: 374). For example, Churchand Bull (1995) evaluate the involvement of employers in assessing students 'presentations. VI. Orality Orality refers to the extent to which the assessment is exclusively oral. Whilst in some cases the assessment criteria centres solely on a spoken presentation, at other times the assessment must be carried out alongside, or be centred on, a written or physical piece

67 of work. Recognition of these dimensions might lead to clearer understanding of the intended purpose of this form of assessment and better implementation. They offer a framework for designing oral assessments according to our intended learning outcomes, and enable university teaching staff to evaluate how relevant to their practice published accounts of approaches to assessing oral communication might be.

1.7 Curriculum Framework for 21 st Century India has made considerable progress in school education since independence with reference to overall literacy, infrastructure and universal access and enrolment in schools. Two major developments in the recent years form the background to the present reform in teacher education the political recognition of Universalization of Elementary Education (UEE) as a legitimate demand and the state commitment towards UEE in the form of the Right of Children to Free and Compulsory Education Act, 2009.

This would increase the demand manifold for qualified elementary school teachers. The country has to address the need of supplying well qualified and professionally trained teachers in larger numbers in the coming years. At the same time, the demand for quality secondary education is steadily increasing.

1.7.1-Context for NCTE's 21st Century Literacy's Framework

The NCTE definition of 21st century literacy's makes it clear that the continued evolution of curriculum, assessment and teaching practice itself is necessary. Literacy has always been a collection of cultural and communicative practices shared among members of particular groups. As society and technology change, so does literacy. Because technology has increased the intensity and complexity of literate environments, the 21st century demands that a literate person possess a wide range of abilities and competencies, much literacy. These literacy are multiple, dynamic, and malleable. As in the past, they are inextricably linked with particular histories, life possibilities and social trajectories of individuals and groups. Active, successful participants in this 21st century global society must be able to: ? Develop proficiency and fluency with the tools of technology.

68 ? Build intentional cross-cultural connections and relationships with others so to pose and solve problems collaboratively and strengthen independent thought. ? Design and share information for global communities to meet a variety of purposes. ? Manage, analyze and synthesize multiple streams of simultaneous information. ? Create critique, analyze, and evaluate multimedia texts. Attend to the ethical responsibilities required by these complex environments. 1.7.2-Elements of the Framework Applied to students of English language arts, the literacy demands of the 21st century have implications for how teachers plan, support and assess student learning. Teachers benefit from reflecting on questions associated with 21st century literacy demands. The demands are: 1.7.2-A-Develop proficiency and fluency with the tools of technology

Students in the 21st century should have experience with and develop skills around technological tools used in the classroom and the world around them.

Through this they will learn about technology and learn through technology. In addition, they must be able to select the most appropriate tools to address particular needs. ? Students use technology as a tool for communication, research and creation of new works. ? Students evaluate and use digital tools and resources that match the work they are doing. ? Students find relevant and reliable sources that meet their needs. ? Students take risks and try new things with tools available to them. ? Students independently and collaboratively solve problems as they arise in their work. ? Students use a variety of tools correctly and efficiently.

69 1.7.2-B-Build connections and independent thought. Students in the 21st century need interpersonal skills in order to work collaboratively in both face-to-face and virtual environments to use and develop problem-solving skills. When learning experiences are grounded in well-informed teaching practices, the use of technology allows a wider range of voices to be heard, exposing students to opinions and norms outside of their own. Understanding the ways in which connections support learning and being intentional about creating connections and networks are important for 21st century learners. The understanding ways are: ? Students work in a group in ways that allow them to create new knowledge or to solve problems that can't be created or solved individually. ? Students work in groups to create new sources that can't be created or solved by individuals. ? Students work in groups of members with diverse perspectives and areas of expertise. ? Students build on one another's thinking to gain new understanding. ? Students learn to share new ways of thinking in ways that positively impact the work. ? Students gain new understandings by being part of a group or team. ? Students open to and intentional about learning from and with others. 1.7.2-C - Design and share information for global communities that have a variety of purposes: Students in the 21st century must be aware of the global nature of our world and be able to select, organize, and design information to be shared, understood, and distributed beyond their classrooms. ? Students use inquiry to ask questions and solve problems ? Students critically analyze a variety of information from a variety of sources ? Students take responsibility for communicating their ideas in a variety of ways

70 ? Students choose tools to share information that match their need and audience ? Students share and publish their work in a variety of ways ? Students solve real problems and share results with real audiences ? Students publish in ways that meet the needs of a particular, authentic audience ? Students consciously make connections between their work and that of the greater community. 1.7.2-D-Manage, analyze, and synthesize multiple streams of simultaneously presented information Students in the 21st century must be able to take information from multiple places and in a variety of different formats, determine its reliability, and create new knowledge from that information. ? Students create new ideas using knowledge gained ? Students locate information from a variety of sources ? Students analyze the credibility of information and its appropriateness in meeting their needs ? Students synthesize information from a variety of sources ? Students manage new information to help them solve problems ? Students use information to make decisions as informed citizens ? Students strive to see limitations and overlaps between multiple streams of information 1.7.2-E-Creat critiques, analyze, and evaluate multimedia texts Students in the 21st century must be critical consumers and creators of multimedia texts. The multimedia texts are: ? Students use tools to communicate original perspectives and to make new thinking visible

71 ? Students communicate information and ideas in a variety of forms and for various purposes ? Students communicate information and ideas to different audiences ? Students articulate thoughts and ideas so that others can understand and act on them ? Students analyze and evaluate the multimedia sources that they use ? Students evaluate multimedia sources for the effects of visuals, sounds, hyperlinks, and other features on the text's meaning or emotional impact ? Students evaluate their own multimedia works ? Students consider their own design choices as much as their choices about text

1.7.2-F-Attend to the ethical responsibilities required by complex environments Students in the 21st century must understand and adhere to legal and ethical practices as they use resources and create information. These are: ? Students share information in ways that consider all sources. ? Students practice the safe and legal use of technology. ? Students create products that are both informative and ethical.

1.7.3-Implications of the Framework for Assessments Assessments need to take into consideration both traditional components and elements that may be different for 21st century student work.

1.7.3. A-Traditional elements of assessment of 21st century student learning The traditional elements for assessing 21st century student work include relevance and reliability of information used in the work; significance of new information or understandings communicated throughout the process and in the final product; effectiveness of the work in achieving its purpose; impact of the work on the audience; creativity or aesthetics demonstrated in the final product; creativity, initiative, and effectiveness demonstrated in solving problems; efficiency and effectiveness of the student's process; and the student's legal and ethical process and behavior.

1.7.3. B-Newer elements of assessment of 21st century student learning Assessment of 21st century products of learning may be different because of technological tools. Some elements to consider include: ? Extent of students' access to 21st century tools both in and out of school; ? Range and depth of information readily accessible to students; ? Facility of students with technology tools; ? Extent to which tools can make artists, musicians, and designers of students not traditionally considered talented in those fields; ? Extent to which images and sound may amplify text; ? Extent to which students understand the power of their connections; ? Extent to which student products can emulate those of professionals; ? Extent to which students receive feedback from experts in the field; ? Potential interaction with and impact on a global audience; ? Students' selection of tools or media that most effectively communicate the intention of the product; ? Students' level of ethical and legal practice as they remix products; ? Level of ethics and safety exhibited in students' online behavior; and ? Extent to which students recognize the impact of their own digital footprint.

1.7.4-Assessment practices of 21st century student learning may need flexibility and responsiveness to situations such as: ? Students' greater proficiency with tools or formats than the teacher, which may generate outcomes not anticipated in an assessment rubric; ? Technology glitches beyond students' control that negatively impact the quality of the final products;

73 ? Scope of collaboration, in the classroom and globally, leading to a greater need for processes that assess progress and achievement of individuals and groups; ? Support and celebration of the increasing diversity in students' talents, imagination, perspectives, cultures, and lived experiences; ? Recognition that the processes of learning and doing are as important as the quality of the final product; ? Students' self-evaluation and reflection on process and product integrated into the learning process and contributing to students' continued growth; ? Ability of students, parents, and teachers to examine growth over time in authentic ways.

1.7.5-Selected Standards for the Language Arts pertaining to 21st Century Literacy ? Students read a wide range of print and non-print texts to build an understanding of texts, of themselves, and of the cultures of the United States and the world; to acquire new information; to respond to the needs and demands of society and the workplace; and for personal fulfillment. Among these texts are fiction and nonfiction, classic and contemporary works. ? Students read a wide range of literature from many periods in many genres to build an understanding of the many dimensions (e.g., philosophical, ethical, aesthetic) of human experience. ? Students apply a wide range of strategies to comprehend, interpret, evaluate, and appreciate texts. They draw on their prior experience, their interactions with other readers and writers, their knowledge of word meaning and of other texts, their word identification strategies, and their understanding of textual features (e.g., sound-letter correspondence, sentence structure, context, graphics). ? Students apply knowledge of language structure, language conventions (e.g., spelling and punctuation), media techniques, figurative language, and genre to create, critique, and discuss print and non-print texts. ? Students conduct research on issues and interests by generating ideas and questions,

74 and by posing problems. They gather, evaluate, and synthesize data from a variety of sources (e.g., print and non-print texts, artifacts, people) to communicate their discoveries in ways that suit their purpose and audience. ? Students use a variety of technological and information resources (e.g., libraries, databases, computer networks, video) to gather and synthesize information and to create and communicate knowledge. ? Students whose first language is not English make use of their first language to develop competency in the English language arts and to develop understanding of content across the curriculum. ? Students use spoken, written, and visual language to accomplish their own purposes (e.g., for learning, enjoyment, persuasion, and the exchange of information). Flow Chart in 21 st Century Pedagogy
<http://w.w.w.note.org/governance/21stcenturyframework>

75 1.8 Let us sum up In education often refers specifically to a planned sequence of instruction or its view of the student's experiences in terms of the educator's or schools instructional goals. Curriculum is incorporated with the plan interaction of pupils with instructional content, materials, resources and processes for evaluating of educational objectives.

In history of education, the term 'curriculum' was originally related to the concept of a course of studies followed by a pupil in a teaching institution.

In fact, the term curriculum is mostly used to refer to the existing contract between societies with regard to the educational experiences that learners should undergo during a certain phase of their lives.

Using educational concepts, we can say that the curriculum defines the educational foundations and contents, their sequencing in relation to the amount of time available for the learning experiences, the characteristics of the teaching institutions, the characteristics of the learning experiences, in particular from the point of view of methods to be used, the resources for learning and teaching (e.g. textbooks and new technologies), evaluation and teachers' profiles.

Curriculum is a comprehensive plan for an educational program to offer new improved manpower to fulfill the rising needs of a dynamic society. Education completes a man.

Students need quality education suitable for life. Perceiving the needs of the learners, appropriate changes are made in the curriculum, syllabus and textbook on a need basis. Currently changes have taken place in the evaluation system.

Evaluation is conducted through activities, observation and group discussion. The evaluation is done under two parts namely scholastic and co-scholastic activities. Scholastic activities have been further classified into two parts viz.

Formative and Summative Assessments. A holistic approach to education at the elementary level is a must as it is the most important subsection of the whole education system. Such an approach will facilitate the total development of a child by providing the right atmosphere for learners to develop and enrich their talent. Building self-concept, self image, sense of enterprise and sportsmanship and so on should be part of the educational process. Therefore, the curriculum is designed giving due emphasis on both scholastic and co-scholastic area.

A Child's holistic development is measured not only by his academic achievements. Sports & Games, Arts & Fine Arts and social skills combined together with intellectual excellence makes a student what he or she will be when he blossoms into an adult. In view of this opens an avenue of Co-Scholastic activities to prepare children with hearing impairment for his greater journey of life. Co-scholastic abilities are not just 'nice to have' or 'desirable to have', but 'must have' qualities.

Co-scholastic activities

like Yoga, Music, Dance, Sports and other activities moulds the wholesome personality in students and implemented for character development in students.

India has made considerable progress in school education since independence with reference to overall literacy, infrastructure and universal access and enrolment in schools.

76 1.9 Let us sum up 1. Write about details in approach to curriculum 2. Write about details in curriculum design for hearing impaired children. 3. Discuss about details curricular input children with hearing impairment in Scholastic areas. 4. What do mean by Scholastic activities. Discuss about details aim, important and scholastic achievement of student with hearing loss. 5. Discuss about details in relevant Areas of Non-Scholastic Assessment in hearing impairment. 6. Discuss about details in of Non-Scholastic Assessment Issue in hearing impairment. 7. Discuss about details Curricular guidelines children with hearing impairment in Non-Scholastic Areas 8. How many type of curricular adaptation in children with hearing impairment in Non-Scholastic areas? Discuss details. 9. Write about details Elements of theCurriculum Framework in 21 st century 10. Write a short note about literacy frame work in 21 st century. 11. Write a short noteabout Language Arts pertaining to 21st Century Literacy's with diagram. 1.10 References i. Elias, M. J. (2006). 78 Unit - 2

Developing Literacy Skills: Reading Structure 2.1. Introduction 2.2. Objectives 2.3. Pre-requisites for reading and emergent reading skills 2.4. Assessment of reading skills at different levels 2.5. Approaches and Strategies to develop reading skills and independent reading 2.6. Types and Models of developing reading skills 2.7. Challenges and Remedial strategies 2.8.

Let's Sum Up 2.9. Check your Progress 2.10. References 2.1 Introduction Reading is a Constructive Process. Reading may be described as "getting meaning" from written text. A reader's skill in comprehension depends on three things: (i) the background knowledge of the reader. (ii) The accuracy with which the reader responds to printed or written material. (iii) The reader understands of the message of the text. "Reading is a language process that involves a dialogue between the reader and the author." (Hedge, 2000). It is a constructive, interactive process which takes place behind the eyes.

Definition of

Reading: Reading is a process of comprehending ideas from printed or written symbols to 79 associate the known meaning with these symbols. Anderson, Heibert Scott and Wilkinson (1985) defined reading as a process in which information from the text and the knowledge processed by the reader act together to produce meaning. 2.2.

Objectives: After studying this unit, the students should be able to Understand the concept of Reading. Understand the concept of prerequisite of reading and types of reading. Understand the approaches and Strategies involved in Developing reading. Understand the assessment of reading skills at different levels of students with hearing impairment. Understand the types and models of developing reading skills. Understand the challenges faced by students with hearing impairment reading and its remedial strategies. 2.3. Pre-requisites for reading and emergent reading skills: Pre-requisites for reading and emergent reading skills: Left to right or Right to left eye-hand-mind coordination. Knowledge of alphabets. Knowledge of pronunciation of symbols(phonetic skills). Ability to visually discriminate the symbol and group them to form word (she i.e. she). Ability to understand the meaning of word within the text. Ability to work out pronunciation of unknown word with the help of spelling.

80 2.4.

Assessment of reading skills at different levels:

Receptive One-Word Picture Vocabulary Test (ROWPVT): The ROWPVT assesses a student's knowledge of vocabulary by asking the child to point to the object being named. The test ends when the child cannot correctly identify the pictured meaning of the word in 6 out of 8 consecutive items. Test of Early Reading Ability (TERA-3): The TERA-3 measures reading ability of young children ages 3-6 through 8-6. Rather than assessing a child's reading readiness it assesses their mastery of early developing reading skills. The three sub tests include: Alphabet (knowledge of the alphabet and its uses), Conventions (knowledge of the conventions of print), and Meaning (measuring the construction of meaning from print). An overall Quotient is computed using all three subtest scores. Test of

Reading Comprehension (TORC): Eligibility for testing: Ages, 0-7 and 11-17 Able to understand directions of subtests Able to formulate the necessary responses Able to read English Administration Time: No time limits The entire test varies from 30 minutes to 90 minutes The average time being an hour Each subtest generally takes 5-15 minutes

81 General Vocabulary: Purpose: to measure the reader's understanding of vocabulary that is related to a general concept Description: 25 vocabulary questions Syntactic Similarities: Purpose: to measure the reader's understanding of meaningfully similar but syntactically different sentence structures Description: 20 questions Paragraph Reading: Purpose: ability to answer questions related to the paragraph Description: 6 paragraphs with 5 questions each Sentence Sequencing: Purpose: measure the ability to order sentences into a paragraph Description: 10 test questions – Consisting of 5 randomly ordered sentences and the reader has to put them in the correct order to form a paragraph. Mathematics Vocabulary: Purpose: understanding of mathematics vocabulary Description: 25 test questions Social Studies Vocabulary: Purpose: understand social studies vocabulary Description: 25 test questions Science Vocabulary: Purpose: understanding of science vocabulary

82 Description: 25 test questions Reading of Directions of Schoolwork: Purpose: measures understanding of written directions commonly found in schoolwork Description: 25 test questions – Consist of a printed command that the student has to carry out on the answer sheet 2.5.

Approaches and Strategies to develop reading skills and independent reading:

Phonics Approach Word recognition is taught through grapheme-phoneme associations, with the goal of

teaching the student to independently apply these skills to new words.

Phonics instruction may be synthetic or analytic. In the synthetic method, letter sounds are learned before the student goes on to blend the sounds to form words. The analytic method teaches letter sounds as integral parts of words. The sounds are usually taught in the sequence: vowels, consonants, consonant blends at the beginning of words (e.g., bl and dr) and consonant blends at the end of words (e.g., ld and mp), consonant and vowel digraphs (e.g., ch and sh), and diphthongs (e.g., au and oy). Critics of the phonics approach point out that the emphasis on pronunciation may lead to the student focusing more on decoding than comprehension. Some students may have trouble blending sounds to form words and others may become confused with words that do not conform to the phonetic "rules." However, advocates of phonics say that the programs are useful with remedial reading and developmental reading. Examples of phonics series are Science Research Associates, Merrill Phonics and DML's Cove School Reading Program.

83 Linguistics Approach In many programs, the whole-word approach issued. This means that words are taught in families as a whole (e.g., cat, hat, pat and rat). The focus is on words instead of isolated sounds. Words are chosen on the basis of similar spelling patterns and irregular spelling words are taught as sight words. Some advantages of this approach are that the student learns that reading is talk written down and develops a sense of sentence structure. The consistent visual patterns of the lessons guide students from familiar words to less familiar words to irregular words. Reading is taught by associating with the student's natural knowledge of his own language. Disadvantages are extremely controlled vocabulary, in which word-by-word reading is encouraged. Others criticize the programs for the emphasis on auditory memory skills and the use of nonsense words in the practice exercises. A sight word, or "look-say," approach: Those who advocate a sight word approach, in contrast to phonics, claim to be concerned that meaning be emphasized from the very outset of reading instruction. They stress helping children develop a stock of words that the children can recognize on sight. Thus instead of stressing letter/sound correspondences and phonics rules, teachers might use flash cards and other devices to help children learn to recognize basic words. Advocates of a sight word approach argue that if children can begin with a stock of about one hundred basic sight words, they will be able to read about half the words in any text they might ordinarily encounter. This approach was widely used from about 1930 until about the mid-1960s, when it became increasingly intertwined with (or permeated by) a phonics approach. Although prominent advocates of the sight word approach commonly expressed concern with meaning, during the heyday of the sight word approach actual classroom instruction came to focus heavily on the identification of words, and this emphasis continues implicitly in many of today's basal readers. Thus, like advocates of phonics, practitioners of sight word instruction as well as the general public reflect the "commonsense" assumption that once words

84 are identified, meaning will take care of itself. The sight word, or "look-say," approach differs from a phonics approach in that it focuses on whole words rather than on parts of words, but in practice, both are concerned more with word identification than with meaning. Today, the sight word approach survives primarily as part of a basal reader program, as a supplement to a basal program (e.g., Developing a Basic Sight Vocabulary), and/or as the labeling of objects in children's homes or the classroom environment. A whole language approach to education is sometimes claimed to be nothing-more than a new name for the sight word approach.; " Basal Reading Basal reader series form the core of many widely-used reading programs from preprimary to eighth grade. Depending on the series, basal readers may be meaning emphasis or code emphasis. Teacher manuals provide a highly-structured and comprehensive scope and sequence, lesson plans, and objectives. Vocabulary is controlled from level to level and reading skills cover word recognition, word attack and comprehension. Advantages: Advantages of basal readers are the structured, sequential manner in which reading is taught. The teacher manuals have teaching strategies, controlled vocabulary, assessment materials and objectives. Reading instruction is in a systematic, sequential and comprehension-oriented manner. Many basal reading programs recommend the directed reading activity procedure for lesson presentation. Students proceed through the steps of motivation preparation for the new concepts and vocabulary, guided reading and answering questions that give a purpose or goal for the reading, development of strengths through drills or workbook, application of skills and evaluation. A variation of the directed reading method is direct reading-thinking, where the student must generate the purposes for reading the selection, form questions, and read the selection. After reading, the teacher asks questions designed to get the group to think of answers and to justify their answers.

85 Disadvantages: Disadvantages of basal readers are the emphasis on teaching to a group rather than the individual. Critics of basal readers claim that the structure may limit creativity and not provide enough instruction on organizational skills and reading for secondary content levels. Basal readers, however, offer the advantage of a prepared comprehensive program and may be supplemented with other materials to meet individual needs. Language Experience Approach The language experience approach is similar to whole language in that reading is considered as a personal act, literature is emphasized and students are encouraged to write about their own life experiences.

The major difference is that written language is considered a secondary system to oral language, while whole language treats the two as parts of the same structure. The language experience approach is used primarily with beginner readers but can also be used with older elementary and with other older students for corrective instruction. Reading skills are developed along with listening, speaking and writing skills. The materials consist, for the most part, of the student's skills. The philosophy of language experience includes: 1 What students think about, they can talk about? 2 What students say, they can write or have someone write. 3 What students write or have someone write for them, they can read. Students dictate a story to a teacher as a group activity. Ideas for stories can originate from student artwork, news items or personal experiences, or they may be creative. Topic lists, word cards or idea lists can also be used to generate topics or ideas for a class story. The teacher writes down the stories in a first draft and the students read them back. The language patterns come from the students and they read their own written thoughts. The teacher provides guidance on word choice, sentence structure and the sounds of the letters and words. The students edit and revise the story on an experience chart. The teacher provides specific instruction in grammar, sentence structure and spelling, if the need arises, rather than using a specified schedule. As the students' progress, they

86 create their individual storybooks, adding illustrations if they wish. The storybooks are placed in folders to share with others. Progress is evaluated in terms of the changes in the oral and written expression, as well as in mechanics. There is no set method of evaluating student progress. That one disadvantage of the language experience approach. However, the emphasis on student experience and creativity stimulates interest and motivates the students. Strategies Involved in the Reading Process Reading is said to be a complex process and takes place in various steps. According to Searfoss and Readnece (1994), reading is a process, which involves four essential cue systems interacting with each other. They are: 1. The Graphophonic Cue System: The graphophonic cue system is the system of relating sounds or phonemes to the symbols or graphemes of print. Therefore learning the names of the letter and the various sounds they stand for is often part of beginning of reading instruction. For example, phonic instructions: words ending with 'at'-cat, bat, rat. 2. The Syntactic Cue System: The syntactic cue system is the set of underlying natural rules by which the language operates. Language is arranged and rearranged according-to' these 'rules. The acquisition of syntactic knowledge is accomplished without being able to state formally the rules of syntax that are used.. The child acquires the pattern of sentence-'Raju wants a ball.' But later on learns that Raju is noun (subject), wants is verb etc. and a sentence in English is generally written in SVO pattern. 3. The Semantic Cue System: The semantic cue system gives meaning to words, sentences and longer units of prints. It is the knowledge, gained through prior experiences, which readers carry around in their heads and bring to ea reading situation. Semantic development includes not on how much vocabulary is acquired, but also how words a used and understood at various stages of cognitive development arid in different context. 4. The Pragmatic Cue System: The pragmatic cue system incorporates the cultural

87 and social aspects of using language. Language is used to perform many functions an: how it is spoken and written varies according to purpose and audience. Language use varies among ethnic group social classes and geographical regions. When all cue systems are present in a reading situation, we can reasonably predict that the reader will be able to construct meaning from the print. Development of these cue systems is crucial to the development of reading skills. 2.6.

Types and Models of developing reading skills Reading instruction is not limited to a single period in a school day.

Reading goes on all day long in relation to all school subjects and activities.

Types of reading can be based on: Purpose, Type of Material, Style of Reading and Level of assistance.

Types of Reading Purpose Developmental Remedial Functional Recreational Type of Material Conversational Text based Style of Reading Loud Silent Level of Assistance Guided

88 Independent Reading based on the purpose:

The reading experiences can be differentiated into four types: Developmental, functional, remedial and recreational. It makes possible to separate and integrate the teaching of reading and the teaching of language through reading. (i) Developmental Reading: (Reading known language) Developmental reading consists of designed and planned reading lessons. Its purpose is to systematically develop and promote sequential skills in reading. Ideally, developmental reading is conducted with material where the language is completely known to the child so that there is no interference with the child's development of mature reading habits and skills. In this type of reading the child is presented with appealing reading material. The teacher observes and guides the child to strengthen the growing skill in reading. This helps the child to learn to use appropriate reading skills to independently figure out the meaning of known language. Whenever unknown language interferes with this process, the teacher takes steps to remove this obstacle. She either pre-teaches the unknown linguistic forms, or freely explains them

during reading and teaches

them in depth afterwards. The early readers and textbooks are especially useful for developmental reading as they provide a gradual progression from easy to more difficult level through grades. (

ii)

Remedial Reading: (Teaching language through reading) The aim of remedial reading is to correct specific language deficiencies. Remedial reading is especially used to promote language, but the activities can serve varied purposes. The teacher can return to the language forms found difficult during developmental reading and teach them thoroughly during remedial reading. The teacher can construct games, exercises and tests for further drill in understanding and use of these linguistic 'forms.

Teachers can find opportunities in activities

and experience for it. Systematic programmes may also be devised to teach aspects of

89 vocabulary (synonyms, antonyms, idioms, multiple meanings, figures of speech etc.), morphology (plural, verb forms, etc.) and syntax (clauses, question forms

etc.)

Remedial reading may also be used to provide drill in specific reading skills. Children who need more practice than is provided in developmental reading may benefit from special remedial activities. Remedial reading thus becomes part and parcel of special education. Also, as language and reading go hand in hand developmental reading and remedial reading

go hand in hand. (iii) Functional Reading: (Reading as means to an end) Functional reading represents reading in its natural form. In functional reading, reading is not the primary activity but there is a task, which is to be completed through reading. E.g. Reading a recipe to make a food item like pulav, follow directions to complete a puzzle, read label to know the owner of a book etc. There are numerous occasions for functional reading-following directions for a new game, putting together things to assemble a toy, comparing weights and prices on boxes of food items etc. All such activities demonstrate the children the importance of reading in life. Functional Reading

at Preschool Level Following activities can be taken: Incidental reading in class (names of biscuits etc.) Writing names on chair. Attendance charts. Health charts. Writing plans for the day/week and reading them. At Primary Level Reading newspapers. Doing activities following instructions (making paper caps, lime juice etc.).

90 Exposing to reading names of streets, names on shops, bus numbers through visits and daily travel from home to school. (iv)

Recreational Reading: (Reading for pleasure and information) Reading to gain pleasure is recreational reading. Structured reading activities

are

usually difficult task for the children. Therefore it is very important to include reading without struggling in the reading programmes. Children should be given daily opportunities to read whatever material they choose, whatever purpose they set for themselves, in whatever way and whatever level of comprehension they are capable of, without adult interference or guidance. Children should be provided with access to good libraries in class, in school and at home.

Attractive book displays, talks with authors, and storytelling sessions help to make reading an enjoyable experience. Such type of reading is very useful for cultivating the 'habit' of reading outside the school world. At the preschool, picture books should be provided. Activities of reading stories to the child can be undertaken. Based on Type of Reading Material The achievement in reading also depends on the type of material. On the basis of the material there are two types at reading.

Conversational Reading Conversational reading is one of the levels of reading proficiency developed gradually in the early school years. It is a transition step from informal to formal reading.

Conversational

reading is the reading of any non-commercial text that deals with the interest and experience of a child or group of children. The teacher writes

the

normal conversation that goes on during the various activities. The words and sentences used in language activities e.g., news conversations and other activities like projects about family, food, holidays, etc. direct experiences through trips, visits, etc. are written on the board, chart, cards or in teacher made books.

The written words correspond to the spoken language and are known to the children, so these words become sight words, i.e., the children recognize and identify the meanings of the

91 written words at sight (audio-visual reading). The teacher then implants these words in the various experiences. Types of Conversational Reading News: The news period is usually a conversational period. Children enjoy telling about their new possessions their places of visit, what they did with their families and friends. The news period offers an excellent opportunity for meaningful repetition of simple language pattern in oral and written form. This reading begins generally with some calendar work to identify the day of the week and the date, attendance and weather. Afterwards the sentences elicited from the students are written. At first, the sentences-ate very. simple stating bare facts. Gradually variations in language can be introduced, always keeping pace with children's progress. 1. For example: Raju said, "I did not eat the ice cream." Mother was very angry. She scolded, "Don't tell lies." News books can also be introduced where the child writes news from the class for the parents and from home for the class. 2. Direct Experience: Conversational reading can be based upon direct experience like. 1. Trips: The teacher can make experience chart about what the children have seen. 2. Activities: After an activity the experience of the children can be elicited from them and written down. The follow-up of experiential reading can be: 1. Books and Stories similar to children's experience. 2. Letter written in conjunction with some activities-to request permission or information, invitation, thank you letter, letters telling an absent child about the trip.

92 3. Making list of things required e.g., for trip, material needed during craftwork, steps carried out to perform an activity. 4. Signs labels and caption for pictures. 5. Teacher made stories based on the children's experiences. The experience chart should be the expression of the children's impressions, discoveries, and reactions. The teacher should act as recorder and co-ordinate the impressions of all the children. These charts should be illustrated as required. The benefit of experience charts is that the children will move easily with the text to read the printed symbols of incidents significant to them. Example of conversational reading: Topic -Visit to the garden Yesterday was a wonderful day. We went to the garden. There were many plants with flowers. Oh what fun, we played on the swing and seesaw. Text Based Reading In the

text based reading the meaning has to explicitly or implicitly drawn from the written words. It means that the meaning may either be clear or may be hidden and has to be understood. In schools teachers \ undertake text-based reading i.e., they impart information and knowledge usually through reading textbooks.

The two types of texts commonly used in schools are: Narrative Text: Text that tells a story or an event is narrative text. Stories come in variety of forms. Reading narrative texts requires readers to keep track of, and remember sequential events, flash back, and cause-effect events. The traits of the key players-human, animals etc. are prominent in a narrative text it has direct descriptions and provide subject matter for comprehension instruction. Narrative text helps the students to acquire interest in reading. Expository Text: Expository text is informational text. A subject textbook like 93 geography, science etc. is composed of expository text material. Articles in magazines and encyclopedia are also expository since they provide information. The structure or composition of expository text usually consists of one or more central ideas that are supported with related details. This is reflected in the headings and subheadings provided in the text. The specific expository style of a textbook varies depending on the information that is being conveyed. The expository text is usually less familiar. The social studies textbooks usually deal with a theme through grades. It is presented in an expository style. While Teaching: Learning from expository text, the context and the text that communicates it have to be dealt with. For successful instruction of the expository text the following is necessary. identification of the important content. identification of concepts and vocabulary that students must know if important content is to be understood and retained. previous knowledge assumed by the author. identifying features of text that might be confusing (For example, figurative language). usefulness of graphic aids included in the text. Expository text needs higher-level skills in comprehension. 3. Procedural Text: Procedural text is composed of description of procedures for doing something, for making something or for getting somewhere. The directions on numerous practice exercises that students are asked to do are procedural text. The purpose of procedural text is to 'read and follow' the directions or procedures exactly so that the desired goal is realized. The students should be provided more opportunities of reading such text through various activities.which may also improve the functional reading skills'in them.

94 Loud Reading and Silent Reading In a classroom situation reading takes place in various forms. When children start reading independently, they are presented with reading material. The reading of these materials in the teaching learning process may be loud or silent. Both oral and silent readings have their own significance in the process of comprehension. Loud Reading: Loud reading refers to reading aloud, i.e., using vocalization for reading. It is also known as oral reading. Oral reading can serve various purposes such as instruction, diagnosis and sharing. Loud Reading

for instruction: Certain instructional objectives for improving comprehension abilities rely on loud reading for their attainment. (a) Instructions about Typographic Signals: Written language is characterized by physical properties (typographic signals) that aid comprehension. The students have to be taught the significance of these signals, which is possible through loud reading. 1. The function of commas. Raju, my friend, is your classmate. Raju, my friend is your classmate. 2. Understanding the supra segmental aspects: Will you do me a favour? This is my new dress. This is my new dress. Thus loud reading demonstrates the importance of careful pronunciation and enunciation of words, appropriate volume, communicating feelings and facts. Loud Reading for Diagnosis: Loud reading can be used in schools for diagnosis- to identify a student's particular abilities and shortcomings. For example: Cues being used with unfamiliar words.

95 Use of contextual cues, spellings etc. Rearrangement of sequence of sounds (felt read as left etc.) Attention given to position of sound (initial, medial, final). Strategy for working out long complicated words. Tendency to omit words or depend on outside help. Understanding the errors made while reading etc. Loud Reading for Sharing: children need to read aloud to share what they have read. For the children who are shy, reading habits can be fostered through group oral reading, which reduces fear. Usually round robin reading-one child reads and others follow it silently) IS practiced in schools. Silent Reading:

The difference between loud reading and silent reading is that loud

reading is heard and silent is not heard. In silent reading subvocalisation is commonly present. Subvocalisation, also called as inner speech is

a mental pronunciation of words that is neither heard nor seen. It is observed that subvocalisation may facilitate the comprehension of difficult material by focusing the reader's attention on meaning.

The primary purpose of silent reading is to get or construct an author's message. Silent reading is assumed to be faster than the loud reading, because the eye movement on the text is faster. This type of reading can be used in classroom instruction when the focus is not on teaching reading and the children know to read. It should be used with increasing grades, as

the children should learn to construct meaning from the text rather than just pronouncing it.

Guided Reading and Independent Reading Variety in reading experience should be provided to the children for maximum effectiveness in reading. Guided and independent reading should always a component of a lesson fostering reading.

Guided Reading: Guided reading is an important step for a lesson. It is useful for

96 monitoring the student's progress. Guided practice can be written or oral. It gives a chance to the students to use what they have learnt while teacher is supervising. Since the students are being observed they can get a prompt feedback.

Wherever the student faces a problem, he can be explained there itself or the lesson can be retaught. The child can be given reinforcement for their performance. Developmental, remedial and functional readings are types of guided reading.

Independent Reading: Independent reading is reading without assistance. Many things that further facilitate growth in reading comprehension ability-general knowledge, vocabulary, and syntactic knowledge are developed through independent reading. This is reading extended pieces of textbooks, magazines, newspapers etc. The benefits of reading independent level material are: It allows for the consolidation and realistic use of what had been taught. It moves attention away from individual words to the meaning of connected text. It fosters good habits in reading. It adds to the reader's knowledge of the world. Promotes self-confidence and arouses greater interest in reading.

Models of Reading: In the last 40 years reading researchers have been studying the link between the reading process (what goes on in the brain) and how to teach reading. Depending on their interpretation of the reading process, they have developed a model of reading. Definition A reading model is a graphic attempt "to depict how an individual perceives a word, processes a clause, and comprehends a text." (Singer and Ruddell ,1985) Here are some kinds of reading models. Although there are many models of reading, reading researchers tend to classify them into three kinds.

97 Bottom-up Top-down Interactive Processing in Bottom-Up Model: Reader builds meaning from the smallest units of meaning to achieve comprehension. Example letters letter clusters words phrases sentences longer text meaning = comprehension Processing in Top-Down Model: Reader generates meaning by employing background knowledge, expectations, assumptions, and questions, and reads to confirm these expectations. Example Pre-reading activities (i.e. activating schema, previewing, and predicting) + background knowledge (cultural, linguistic, syntactic, and historical) = comprehension Processing in Interactive Model: Reader uses both bottom-up and top-down strategies simultaneously or alternately to comprehend the text. Example Reader uses top-down strategies until he/she encounters an unfamiliar word, then employs decoding skills to achieve comprehension. 2.7. Challenges and Remedial strategies: Students with hearing impairment and reading Students with hearing impairment, like hearing children, need to learn how to read and understand stories, passages and sentences from all subjects in school. They have to be able to distinguish the important facts and ideas from words they are

98 reading and identify which words are unimportant. Sometimes this is difficult for Students with hearing impairment because they are reading words or sentences they cannot understand. Some Students with hearing impairment will simply read each word, without understanding the meaning of what the words are conveying. It is important to check they understand what they are reading by questioning the child on the vocabulary, asking them to repeat the passage in their own words, asking them to draw or act it out and/or by asking the child questions about what they have read. What are some ideas for developing Students with hearing impairment enthusiasm for reading and writing? Read books to the Students with hearing impairment every day.

The books should be age appropriate and interesting. Reading together will improve the child's vocabulary, develop visual skills and assist in reading comprehension. They will begin to develop a love of books. This can be varied by asking the child to read a section, and then adults read a section, or both can both read at the same time. Don't put pressure on your child to read books which are too difficult or if they really don't want to. Instead let your child know indirectly that reading is encouraged, for example, let them stay up a little later on the condition that they read. Encourage an "enjoyment of reading by sharing the book together and talking, commenting on and questioning the story as it is read. Make a journal. Each day, write a short passage about anything at all, something experienced something which will happen, something noticed, etc. The deaf child reads what is written, and then writes back. Don't correct the spelling, punctuation or grammar in this journal. It is simply a "communication book" to support the development of positive attitudes towards reading and writing. Write notes to the

Students with hearing impairment instead of telling them

99 what is wanted. Ask them to write a note in reply. Write down where they will find a surprise. Read a story together and then together, use the theme of the story to make a new version or a new ending. Let your child dictate a story and you write it down or type it on the computer. Check frequently with your child that the meaning is correct. Ask your child to read the story along as you write it down. Your child can illustrate the story if they wish to. Keep these in a special folder for reading together later. Your child can write about pictures, photos, write letters, emails and shopping lists. Be a role model. Let the child see adults enjoy reading. Provide plenty of reading material, both for enjoyment and reference, in the home and make sure there is a special place for the deaf child's books. Join the local library and visit often. Establish a "reading time" for a short period each day to focus only on reading. Make it pleasurable. Always watch the television or DVDs with captions. 2.8.

Let's Sum Up In this sense reading goes on long relation between school subject and activities. So, one needs to learn and understand the content matter. It is the most important factor for a student with hearing impairment. That is why reading skill is a most important factor of student with hearing impairment became with the help of reading skill student with hearing impairment understand the meaning of a word and conveying the inner meaning of the text passage.

100 2.9. Check your Progress 1. Define reading. What are the prerequisites of reading? 2. Describe in brief about the various assessment tools for reading skills of students with hearing impairment. 3. Describe in detail about various types and models of reading. 4. What are the strategies followed in developing reading? Describe approaches to develop reading skills. 5. Write the challenges faced by students with hearing impairment while reading. Discuss its remedial strategies in detail. 2.10. References Anderson, R. c., Heibert, E., Scott, J., & Wilkinson, 1. (~985). Becoming a nation of readers: The report of the Commission on Reading. 101 Unit - 3

Developing Literacy Skills: Writing Structure 3.1. Introduction 3.2. Objectives 3.3.
Pre-requisites for writing and emergent writing skills 3.4. Assessment of written language at different levels 3.5.
Components and types of writing 3.6. Steps and Strategies in Developing Writing 3.7. Challenges and Remedial Strategies
3.8.

Let's Sum Up 3.9. Check your Progress 3.10. References 3.1 Introduction Writing is an act of communication and a
purposeful means of addressing an audience. It is not only writing a sentence but an activity of producing a text in a
context. Writing as an act that takes place within a context, that accomplishes a particular purpose, and that is
appropriately shaped for its intended audience (Weigle, 2002). It means writing is not only as the product of an individual
but also as a social act because writing is activities that are socially and culturally shaped and individually and socially
purposed. Writing needs some process of thinking. By knowing the process of writing, students can develop their ability
to create a good written text. Writing is a process of thinking in which writers figure out their thoughts then put them into
written language (Brown, 2001). During the process of thinking that sometimes needs a long time, the writers are asked
to explore their knowledge, experiences, or memories to find and then determine a topic to write. Furthermore, Harmer
(2004) sees writing as a kind of process wheel, where the writers move both around the circumstance of the wheel and
across the spokes. It describes the complex stages that the writers need to go through to write something.

102 Each stage can be continuously repeated until the writers feel no need to go to the previous stages. Based on the
above definitions of writing, it can be concluded that writing is an act that takes place within a context, which
accomplishes a particular purposes a-relatively permanent record of information, opinions, benefits, feelings, arguments,
explanations, and theories. In addition, writing is also a process of developing ideas into a coherent written language. 3.2.

Objectives: After studying this unit the students should be able to : Understand the concept of
writing Understand the concept of prerequisite of writing, components and types of writing Understand the Steps and
Strategies involved in Developing Writing Understand the assessment of written language at different levels of students
with hearing impairment Understand the challenges faced by students with hearing impairment while writing and its
remedial strategies 3.3. Prerequisites of writing and emergent writing skills: Various activities should be given to the
children from a very early age to develop the skills of writing. Some of the Prerequisites are: Good Observation: Good
observational skills are needed to be developed right from an early age. They should be exposed to various things in the
house, environment, etc. They should be exposed to various pictures, story books to relate and understand things around
them. Various exercises can be given for finding out what is missing in the picture, finding out what is wrong in the
picture, completing the given picture etc. Good Eye Hand Co-ordination: Eye hand co-ordination should be developed
to have good writing skills. Small children could be given various activities

103 like water play, stringing beads together, lacing and swing boards, butting and zipping, etc. Developments of
fine motor skills: Gross and fine motor skills should be develop in the children to enable them to hold a pencil and write
properly.

Activities like piling of blocks, stringing beads, picking up lumps of sugar, sorting dal and grains can be taken. Also playing,
tracing in damp sand, clay and plasticize would help in developing gross and fine motor skills. The children should also
be given a lot of scribbling and colouring exercises. Development of pattern perception: Development of pattern
perception is also very important aspect for learning to write. Activities like sorting block, beads etc. according to the
shapes, colours, sizes can be undertaken. Placing the items in order, completing the given pattern can be given to the
children. The children can also be asked to move things along a given line or move their fingers along the given pattern.
Good Memory: Writing also requires a good memory, recall and ability to recapitulate. Without these, the children will
not able to write on their own. For this, memory games could be taken like placing things in the same order,
remembering the sequence, remembering various actions, pattern writing etc.

Regular Practice: Foe developing writing skills the children should regularly practice at

the school and home. They should do various activities at the home also to develop good eye hand co-ordination, fine motor skills, memory, etc. Only with regular practice and repetition the children will be perfect. It is very important for the children with H.I to develop this habit right from an early age, as they tend to forget very fast. Language Development: It is a very important prerequisite for writing. The child could express himself adequately through writing only if he has base of good language, so it has to be developed adequately from the beginning.

Reading Comprehension: It is also necessary that the reading comprehension
104 of the child be developed.

Only if the reading skills are developed the children would be able to write. 3.4. Assessment of written language at different levels: Writing is one of the most complex and difficult tasks for all students. At a basic level, writers must produce letters, words, and sentences that are readable by an audience by an audience. In other words, they must know the conventions of spelling and punctuation and use appropriate vocabulary and syntactical structures. At a higher level, they must be able to select topics, plan and organize ideas, and make decisions about the information to provide their audience (Powers & Wilgus, 1983). Several authors (Moore, 1996; Paul, 1998) have commented on the difficulty that students with hearing impairment have writing in English. Because of difficulty accessing and learning English syntactical and morphological structures, either auditorily or visually, they make numerous errors at the sentence level. In addition, because many students with hearing impairment have difficulty with reading, their exposure to models of good writing may be limited. Research on the writing of school-age students with hearing impairment shows that they display considerable delays when compared with hearing classmates. The assessment of written language at different levels is discussed below.

Oral and Written Language Scales (OWLS) The OWLS assesses higher order thinking, semantics, syntax, vocabulary, and pragmatics. It includes a Listening Comprehension Scale (picture pointing), an Oral Expression Scale (answering questions, and sentence completion) and a Written Expression Scale (use of conventions, syntactical forms, and ability to communicate meaningfully). TOWL-4: Test of Written Language-

Fourth Edition Ages: 9-0 through 17-11 Testing Time: 60-90 minutes

105 Administration: Individual or Group The fourth edition of Test of Written Language (TOWL-4) is a norm-referenced, comprehensive diagnostic test of written expression. It is used to (a) identify students who write poorly and, therefore, need special help, (b) determine students' particular strengths and weaknesses in various writing abilities, (c) document students' progress in special writing programs, and (d) measure writing. Subtests The TOWL-4 has two forms (i.e., Form A and Form B), each of which contains seven subtests. The sub tests represent the conventional, linguistic, and conceptual aspects of writing. Subtests 1-5 use contrived formats; subtests 6-7 use a spontaneously written story to assess important aspects of language. The subtests are: Vocabulary - The student writes a sentence that incorporates a stimulus word. E.g.: For ran, a student writes, "I ran up the hill." Spelling - The student writes sentences from dictation, making proper use of spelling rules. Punctuation - The student writes sentences from dictation, making proper use of punctuation and capitalization rules. Logical Sentences - The student edits an illogical sentence so that it makes better sense. E.g.: "John blinked his nose" is changed to "John blinked his eye." Sentence Combining - The student integrates the meaning of several short sentences into one grammatically correct written sentence. E.g.: "John drives fast" is combined with "John has a red car," making "John drives his red car fast." Contextual Conventions - The student writes a story in response to a stimulus picture. Points are earned for satisfying specific arbitrary requirements relative to orthographic (E.g.: punctuation, spelling) and grammatical conventions (E.g.: sentence construction, noun-verb agreement).

106 Story Composition - The student's story is evaluated relative to the quality of its composition. 3.5. Components and types of writing: Writing is an

ongoing process. It is necessary to develop interest of the children in

reading and writing from an early age. A sound base of language and reading habits would help a child to express himself or herself independently. There three types of writing. 1. Copying 2. Guided writing 3. Independent writing 1. Copying:

It means observing, looking and doing the same. It calls for imitation of the same pattern and do the same accordingly. At the beginning, the children could be asked to imitate gesture, or actions. Teachers can play games of imitation like clapping hands, jumping, putting hands up etc. Later children could be asked to imitate the teachers' action song, words or sentences. The children gradually learn to copy various things. They would also learn to copy the patterns in the sand, blackboard with their fingers. Activities like placing

of beads, blocks from left to right in a line, would also be taken for copying. Copying patterns with matchsticks is an enjoyable experience. Step by step children should be encouraged to move eye-hand coordination, pattern perception skills and development of fine motor skills should be developed amongst the children. Various age appropriate exercises can also be given to the children like: Copying the pictures and colours Joining dots to complete the picture Copying the alphabets

107 Joining the dotted words Tracing over the patterns Copying the whole word Copying the short phrases and sentences altogether

Copying the short passages, stories, conversations, picture description etc. 2.

Guided writing: After the children learn to copy patterns, pictures, words, sentences from the blackboard, charts or books, they can be slowly guided to start writing their experiences. In special schools the teacher's guide the children to write words, phrases, sentences after a news or conversation, directed activity or visit. The teacher can also provide clues and guide the children to expand on a given topic or printed form.

The teacher can guide the children to read instructions and solve various writing exercises and answer the questions.

Various

exercises can also be given to the children based on stories, passages or picture talks. Later, the teacher can guide the children for writing passages and essays on a given topic. Various

exercises can be given to the children

for developing guided writing like: Choosing and writing the words, sentences correctly by looking at the objects or pictures. Writing various words related to a given word.

e.g. Mango the words made would be fruit, raw, red, sweet, sour. seed etc. Rebus game For example, + cil= Pencil

Writing one word answer, short answer, long answer based on the passage

prepared on conversations, visits, textbooks etc. Circling/underlining/ filling the proper noun, verbs, adverbs, adjective from the given choices. Sequencing a conversation/story

108 Writing sentences in various tenses Forming various questions for underlined word/phrases 3.

Independent writing: Once the children are guided to write slowly and steadily, they need to be weaned from guided to independent writing. Children have to think, reason out and write from their memory, relating it to their experiences. The writing process consists of composing, spellings and handwriting. Composing involves planning and expressive language skills. 3.6.

Steps and Strategies in Developing Writing: The process of writing is a good way to know students' ability and creativity in expressing their ideas. Students need to be aware of the writing process. It is because composing is a series of stages that can vary in sequence and are often recursive, even though they must be ordered in certain ways in a text. Focusing on the process does not mean that the result of writing is not important. The final written product could be the written evidence of the writers' creativity. In other words, it can be said that a good process will lead to a good result. To develop the topics in a good process, there are some ways to go through (Brown, 2001). The writing process that is the stages the writer goes through in, order to produce something in his final written form. There are four-steps in the writing process- planning, drafting, editing and final draft (Harmer, 2004). Each step is described as follows: Step 1: Planning In planning stage, students plan and decide what they are going to write. They start gathering information and ideas for writing by making notes or planning in their minds. While planning, they consider three main aspects i.e. the purpose of the writing, the target group or audience they are writing for and the content structure which they have decided to include.

109 Step 2: Drafting In this stage, they write tentative ideas which are related to the topic that they are going to write without paying attention to the errors. Step 3: Editing (reflecting and revising) After making draft, they re-read their draft to see where it works or not. Perhaps the order of the information is not clear or the sentence is ambiguous. The process of editing may be taken from oral or written comments by peers or teachers. They will help the students to make a revision of their writing. Revising is looking back over what has been written. Step 4: Final version The students make a change of their work after the process of editing. The final product may be different from the first draft after going through some steps. All of the writing process above cannot be separated because those are elements in composing a good written text. Writers are made as well as born. Teachers who give time and energy, lots of practice and stimulus and who foster good writing will reap great reward in the classroom. The management of the writing class needs to be flexible and meet the needs of the strategies in developing writing of the children. It is most important therefore to understand those strategies. They can appear to have different labels in academic writing but are basically similar in description. Pre-Emergent Writing: The child at this stage has no great alphabetic understanding and so cannot decode letter-sound relationships. He will mainly scribble and use symbols and signs and very often will show evidence of letters in various places on the page. At this scribble stage the child will have a good understanding that communication of a message is at work. Knowledge of story content and structure will also be present at this stage. Personal stories, sentences or phrases for pictures will be based on experiences both real and imaginary. Most children will begin to develop phonemic

110 awareness and begin to write some letters but will use reversals and other common mistakes. As he progresses to word writing, spacing, directionality and even invented spelling the confidence grows. Some basic sight words will be used from memory. Children at this stage will greatly benefit from teacher modelling of this process and a consistent use of the Language Experience Chart. Emergent Writing: At this stage the child will have had experience of the different stages of phonological awareness and will have the ability to replace phonemes to make new words e.g. cat to mat. The letter order within words may not be fully developed and reversals may still occur. The child will write full sentences but very often the pattern is the same and each sentence will have the same beginning or ending. Very often at this stage it is difficult to maintain a topic and so the sequence may vary. Experiences with literature and use of books will begin to change the way in which the child writes and so style will develop and an experimental use of punctuation. Ideas and opinions are evident at this stage and a variety of genres should be explored. Early Writing: At this stage sentence construction develops further and more complete thoughts are evident. Practice at expanding sentences and use of descriptive words will help here. The maintenance of the topic has improved and the related sentences will be seen. The length of the piece of writing will have changed. Approximate spelling will still be used but evidence of spelling patterns will also help the child to attack difficult words. Work done on story structure will show here, as character, setting and action will form the basis of story writing. A good grasp of the "who," "doing what", and "where" will become habit. Pictorial recording will still be common. Help will be needed with simple editing and use of editing symbols will foster independence in this area. Developing Writing: Expanding story writing will include character, setting, plot, time and very often a personal response. Greater evidence of fluency in spelling will be a feature here

111 including knowledge of silent letters and homonyms. Punctuation will be seen here also but it will not be fully developed. Greater detail and more descriptive writing will develop. Exploration of a greater variety of writing styles and genres will begin and lots of practice is needed here. Constant practice at editing and redrafting will continue to develop independent writing. Established Writing: At this stage beginning, middle and endings are clear. A greater sense of audience and purpose influences the writing. Sentence construction, has developed even further and more complex sentences will be found. The use of paragraphs will show good sequence as a piece is introduced, developed and concluded. Editing and redrafting should be well developed as the child revises use of grammar and punctuation, but also revisits written ideas. Spelling will be more consistent and use of dictionaries and a thesaurus will be evident here. Story-writing elements will be more developed here, as resolution of problems and dialogue will be mixed with persuasive writing and clear personal responses. 3.7. Challenges and Remedial Strategies: There is a strong relationship between language, reading and writing. Hearing children usually start school with a strongly developed language; they know how language works, how it fits together to make correct sentences, they know the purpose of language and they have many words to express themselves. Language has given them a link to the outside world and through language they will have developed a strong general knowledge base. They can question, debate, argue and reason and use language to control the world around them. But due to lack in hearing, students with hearing impairment are significantly delayed in language and written expression; many teachers have struggled with ways to assist their students when writing paragraphs. Often the students struggle with prewriting skills where they are to formulate and organize their ideas before writing. This is the most creative step in the writing process.

112 Sometimes students with hearing impairment will have errors in grammar, tenses and word endings. Writing sentences with correct sentence structure depends on having an understanding of how our language fits together. They show through their written work that they may have gaps in their understanding of how language works. Many students with hearing impairment have wonderful ideas and it's at this stage they become motivated to write. Once their ideas are organized, they are then ready to write, but English syntax, grammar, and word order complicate the process often leading to the student's frustration and loss of interest in writing. Students with hearing impairment will often need repetition of correct usage of different sentence structures so they can gain a clear understanding of how words fit together to make sentences correctly. They will need to have encouragement so they gain confidence in written expression. Often students with hearing impairment prefer to write about facts they know rather than to use their imagination. There is some evidence that young students with hearing impairment may have limited opportunities for imaginary play and this limits the development of their imagination. Reading requires imagination as each word adds to the picture building in the reader's mind. Interactive Writing Strategies: Interactive Writing Strategies was created in 1991 by a research group from The Ohio State University and from Columbus, Ohio (Fountas, McCarrier, & Pinnell 1994). Interactive writing was developed from Moira McKensie's work with shared writing and from the language experience approach by Ashton- Warner (Collom, Tompkins 2004). During shared writing and language experience the teacher acts as scribe for the students. Interactive Writing differs in that the teacher and the students work together to write a text, or as the literature calls it "sharing the pen". This allows the students to take an active role in the writing process while the teacher scaffolds the support given to the students (Button, Johnson, & Furgerson 1996). During Interactive Writing students use their skills in language, conventions of print, and how words work to create meaningful writing and become competent, independent writers (McCarrier, Imnell, & Fountas, 2000).

113 Strategic and Interactive Writing Instruction (SIWI) Strategies: SIWI largely involves guided and collaborative writing. Students work along with the teacher to co-construct, monitor and edit a piece of text. When the group reaches a consensus to add a phrase or a sentence to the text, the teacher writes the students' word for word expressions (including grammar and meaning errors as they are communicated) on an essay. The teacher then opens the floor for further generation of ideas, or the beginning of revising or editing dialogue. Writing as a recursive process is demonstrated, for participants fluidly move back and forth between ideal text generation, revising and editing. The teacher provides scaffolding and support to students in performing tasks beyond their current levels, with the expectation that students will gradually appropriate: these skills and strategies for independent use. As students grow in confidence, the teacher will move to paired or small group writing and then independent writing. SRWI consists of two major instructional components: (a) the use of writing process strategies or strategic writing instruction and (b) apprenticeship in writing through guided and interactive practice or interactive writing instruction. (a) Strategic writing instruction: SIWI is strategic in the sense that students are introduced to the approaches of expert writers through the use of word or symbol procedural facilitators. These are temporary supports in place to guide students' planning of successful action around writing processes. It is intended that students become deliberate writers during all parts of the writing process. (b) Interactive writing instruction: SIWI is designed to apprentice students in the construction of text through interactive or discursive instruction using an activity format comparable to the adapted format. The collaborative format of SIWI provides a way for teachers to transfer the control of writing processes and strategies over to students. Students are exposed to the thinking, words and actions of more-knowledge able-writers in the context of activity and, over time, appropriate these for their own. Power Writing Strategy: It is a writing strategy adapted from J.E.Sparks Write for Power. It is a framework

114 or strategy that can be used By teachers at all grade levels and across all content areas to, teach writing. Through the implementation of graphic or visual organizers, Power Writing develops organization and communication skills while providing a consistent formula for writing paragraphs. Each paragraph contains: 0 - Background, 1 - Main Idea, 2 - Details, 3 - Supporting Details. Power Writing has 4 steps/writing levels. Step 1, beginning paragraph writing: The student writes about the main idea, adds three detail sentences, and concludes with a closing remark about the main idea. The student follows the 1-2-2-2-1 format. Example: 1 Junk Food I Enjoy (Main Idea) 2 Brownies (Detail) 2 Pizza (Detail) 2 M&M's (Detail) 1 Favorite Foods (Main Idea Restated) I really like three kinds of junk food. I love brownies. I also like pizza. I think M&M's are awesome. I love junk food. Step 2, adding more details: When a student has become proficient at Step 1; he is ready to add more details in his writing. It's time to go to Step 2. Step 2 introduces number 3 which is another supporting detail. It follows a 1-23-23-23-1 format. Example: 1 Junk Food I Enjoy (Main Idea) 2 Brownies (Detail) 3 Lots of Chocolate (Supporting detail) 2 Pizza (Detail)

115 3 Pepperoni (Supporting detail) 2 M&M's (Detail) 3 Red ones (Supporting detail) 1 Favorite Foods (Main Idea Restated) I really like three kinds of junk food. I love brownies. They have lots of chocolate in them. I also like pizza. Pepperoni is the best! I think M&M's are super. I always eat the red one first. I love junk food. Step 3, adding background information and more details: It follows a 001-233-233-133 format. 0 Night (Background) 0 Hungry (Background) 1 Junk Food I Enjoy (Main Idea) 2 Brownies (Detail) 3 Lots of Chocolate (Supporting Detail) 3 Warm Inside (support Detail) 2 Pizza (Detail) 3 Pepperoni (Supporting Detail) 3 Thick Crust (Supporting Detail) 2 M&M's (Detail) 3 Red Ones (Supporting Detail) 3 Bags and Bags (Supporting Detail) 1 Favorite Foods (Main Idea Restated) 3 Eating all day (Detail) 3 Tastes great (Detail)

116 It was late at night. I was really hungry. I thought about the three kinds of junk food I like to eat. I love brownies. They have lots of chocolate in them. They make me feel warm inside. I also like pizza. Pepperoni is the best. I like pizza with a thick crust. I think M&M's are super. I always eat the red ones first. I could eat ten bags of them. I love junk food! I could eat these foods all day. They taste great. There is a Step 4 for more proficient writers that follow a 001-2333-2333-2333-1333 format. In conclusion, because this writing strategy is so visual and follows the same format story after story, the students have been able to write paragraphs with amazing ease. After teacher modeling as a shared writing activity, students with hearing impairment quickly become familiar with the format. 3.8. Let's Sum Up Writing is an act of communication and a purposeful means of addressing an audience. In this unit basic prerequisites have been discussed thoroughly. Three basic types of writing along with steps and strategies like pre-emergent writing, emergent writing, early writing, developing writing are also mentioned in this unit. Students with hearing impairment faced various challenges while writing but strategies like SIWI, Interactive writing and Power writing makes them independent writer. 3.9. Check your Progress 1. Define writing. What are the prerequisites of writing? 2. Describe in brief about the various assessment tools for writing of students with hearing impairment. 4. Describe in detail about types of writing. 5. What are the steps followed in developing writing? Describe the strategies involved in developing writing. 6. Write the challenges faced by students with, hearing impairment while writing. Discuss its remedial strategies in detail.

Introduction

There is no recipe for adapting general education curriculum to meet each student's needs. Each teacher, each student, each classroom is unique and adaptations are specific to each situation. Keep in mind that curriculum does not always need to be modified. By providing multi-level instruction you will find that adapting a lesson may not always be necessary. Differentiating instruction and providing multiple ways assess allows more flexibility for students to meet the standards and requirements of the class. At other times, the curriculum can be made more accessible through accommodations.

We all know that children with hearing impairment often have inadequate language in all forms especially in spoken or written. They find it

difficult to understand the information given in text books or other material. They also find it hard to understand what the teacher teaches, if their learning style and mode of communication does not match the

119 teachers teaching style and

mode of communication. The only way to overcome this difficulty is to make teaching learner centric via use of simple

terms or providing a glossary, avoiding use of complex sentences and saying things in simpler sentences

or reorganizing the language in a way that child finds it easier to comprehend. Illustrations and diagrammatic

representations could also be used with the help of teaching aids. Many examples may be given visually, orally or

in writing to make the information clear; in this way the child would be able to learn even the difficult and higher order

concept. All such improvisation in materials and methods to assist the process of learning constitute

curriculum adaptation. 4.2

Objectives After going through

this unit

you will be able to ?

Understand the

meaning

and principles of curricular adaptation. ?

Conduct necessary assessment and make decision for adaptation. ? Understand the area of

adapting curriculum- content, teaching-learning material, and instruction. ? Understand types of adaptation and process.

? Discuss adaptation and accommodations in student's evaluation and examinations 4.3 Curricular

adaptation-meaning and

principle Adaptations in its lay terms mean the act of fitting in a situation. Curriculum adaptation of, curriculum when planned well

will certainly benefit all

pupils, not just those with special needs.

The adapted curriculum should be helpful and advantageous to the

students. It must be feasible for the teacher and the system to implement. For children with special needs, the curriculum

should be planned in such a way that it inter-relates the facets of classroom services special support services and

personnel and co-curricular activities. Which can facilitate Curriculum integration in its most specific situation. The needs

of learners with specific disabilities are varied. They should be given an

120 opportunity to have access to curriculum throughout the school span just like their age mates. The learning

atmosphere should be such as to generate self motivation, and self- monitoring among the learners. The instructional

materials developed should create conducive conditions and provide experience to the learners. The adapted curriculum

should be such that it suits the needs of the deprived, the disadvantaged and the challenged view to bringing them at par with other

students. Several writers have described appropriate procedures for adapting curriculum and instruction.

The steps identify by

Deschenes et al (1999); Dettmer et al. (2002), Hoover and Patton 1997 can be summarized as: • Selecting the subject or topic to be taught; identifying the specific content to be included; •

Deciding on the way the lesson will be organized and conducted for most students; repairing any

necessary adaptations (

e.g.

shorter assignments, easier textbook, extra use of concrete materials) Teaching the lesson., along with necessary

additional changes. • Providing extra assistance to certain students while the lesson is in progress.

Adaptation can, be made in different areas

like the entire curriculum. Itself or different areas of curriculum like the text book material or resources, teaching

strategies and assessment. However It is also

recommended that adaptations and modifications should not be used unless absolutely necessary and should be faded as soon as possible in order to make the student independent at later stage of schooling. Before proceed further we will discuss about the meaning and differences of adaptation, accommodation and modification. ?

Curricular Adaptations are changes permissible in educational environments which allow the student equal opportunity to obtain access, results, benefits, and levels of achievement.

These adaptations consist of both accommodations and modifications.

Some curricular adaptations do not fundamentally alter or lower standards or expectations in either the instructional or assessment phases of a course of study and can be designated as "accommodations."

These accommodations provide access to participate in the Least Restrictive Environment (L.R.E.) and an opportunity to demonstrate mastery of performance standards.

Some adaptations do alter or lower standards or expectations and can

121 be termed "modifications." These modifications, although providing access, will necessitate careful selection of assessment components to achieve accountability for performance.

General Principles in adapting the Curriculum and Selecting the Curriculum Content 1

Breadth and Depth Considering the total development of the children and time constraint, attention needs to be given to maintaining a good balance in the curriculum in terms of breadth and depth when making adaptations or when designing learning materials for the children. Neither of these elements in the curriculum should be emphasized to the exclusion of the other. 2 Continuity Change in levels, particularly from the primary to the secondary, change of schools and change of teachers may possibly leave gaps in the children's knowledge, which are often an obstacle to progress in learning. To ensure continuity, the teacher needs to identify these possible gaps in individual children through assessment and take remedial action to bridge these gaps without, however, neglecting the general progress of the whole class. 3 Previous Knowledge Learning is often easier and more effective when built upon previous knowledge. It is therefore important that the teacher should identify the previous knowledge of individual children in specific subjects and establish their baselines. Plans as to what learning materials and teaching approaches to use can then be formulated. This will not only bridge possible gaps in the children's knowledge but also avoid unnecessary overlapping of learning materials. 4 Individual Differences Though basically schools and classes for hearing impaired children are encouraged to follow the mainstream curriculum with adaptations, consideration needs to be given to

122 individual differences in the children in terms of ability and interest so that individual learning materials can be designed. 5 Communication Competence As the ability to communicate is a prerequisite skill both in studies and in everyday life, every effort needs to be made to develop communication competence in the children. 6 Residual Hearing There is a general misunderstanding that hearing impaired children cannot perceive sounds whereas in fact most of these children have residual hearing. With sufficient training given to the children and with the help of effective amplification equipment, their use of residual hearing will help to improve their abilities to perceive sounds in the environment, which in turn will be helpful to language development. Therefore, the teacher needs to encourage the children to maximize their use of residual hearing for language development. Language Across the Curriculum The learning of language should not be confined to language lessons only. Instead, it should be extended across the curriculum. Spontaneous language situations can be built casually into the lessons of other subjects to motivate the children to practise using the language for communication purposes. However, this should not be overdone, or these lessons will be turned into language lessons. 4.4

Need assessment and decision making for adaptation If the IEP team decides that a child needs a particular modification or accommodation, this information must be included in the IEP. Supports are also available for those who work with the child, to help them help that child be successful. Supports for school staff must also be written into the IEP. Some of these supports might include: ? attending a conference or training related to the child's needs, ? getting help from another staff member or administrative person,

123 ? having an aide in the classroom, or ? getting special equipment or teaching materials.

Assessments: Assessments are procedures that are individualized for each student. An Educational Institution may use a variety of assessment tools and strategies to gather sufficient relevant functional, developmental, and academic information about the child. This information may assist in determining if the child is a student with a disability

and the content of the child's IEP. Academic information includes your child's progress in the general curriculum, or for a preschool child, participation in appropriate activities. Assessments include printed tests, observations, information from parents, as well as other sources of information that are: ? Selected and administered in a way that is not racially or culturally discriminatory; ?

Administered in the child's native language or other mode of communication and in the form most likely to yield accurate information on what the child knows and can do academically, developmentally, and functionally, unless it is not feasible to do so; ? Used for the purposes for which the assessments or measures are valid and reliable; ? Are administered by trained and knowledgeable personnel

according to the

instructions provided by the producer of the test; ? Tailored to identify specific areas of educational need, not merely to provide a single general intelligence quotient;

and ? Selected to accurately reflect a child's aptitude or achievement, rather than the impaired sensory, manual, or speaking skills, except where these skills are the factors that the test is to measure. Each report of assessment procedures shall include: ? A description of the child's performance in each area of suspected disability; ? Relevant functional, cognitive, developmental, behavioral, and physical

124 information; ? Instructional implications for the child's participation in the general curriculum or, for a preschool child, participation in appropriate activities; and ? For any assessments not administered under standard conditions, a description of how it varied from standard administration procedures.

Initial Evaluation: The initial evaluation shall be comprehensive enough to ensure a child is assessed in all areas related to the suspected disability, including, if appropriate: ?

Academic performance ? Communication ? General intelligence ? Health, including hearing and vision ? Motor abilities ?

Social, emotional, and behavioral status No single procedure is used to determine if

a child is a student with a disability and to determine an appropriate educational program for the child.

A child may not be identified as a student with a disability in need of special education and related services if the determinant factor is: ? A lack of appropriate instruction in reading, including the essential components of reading instruction, which are:

A Curricular Adaptation and

Decision-making Process This

decision-making flowchart can

be used to conceptualize the proces of selecting and implementing curricular adaptations. It should be used as a tool for a team in determining an individual student's needs.

Identify the student's individual educational goals and objectives to be emphasized during general education activities

125 Next Articulate the expectations for the student's performance in general education activities

Next

Determine what to teach As a team, determine the content of the general education activity, theme or unit study Next

Determine how to teach As a team, determine if, without modification, the student can actively participate and achieve the same essential outcomes as non-disabled classmates. If the student cannot achieve the same outcomes... Next

Curriculum Adaptations

It is important to correlate adaptations with the IEP. In other words, we are not adapting for adaptations sake but, to meet the student's needs as identified

on an IEP. a. Curriculum as is. This is

the

type we forget most frequently. We need to constantly

126 be looking at the general education curriculum and asking if the students on IEPs may gain benefit from participating in the curriculum as is. We need to keep in mind that incidental learning does occur. Curriculum as is supports outcomes as identified in standard curriculum.

b. Different objective within the same activity and curriculum. The student with an IEP works with all the other students in the classroom participating in the activity when possible but, with a different learning objective from the other students. This is where the principle of partial participation fits. Examples include: ? A student with a short attention span staying on task for 5 minutes. ? Using a switch to activate a communication device to share during a class discussion. ? Expressing one's thoughts by drawing

in a

journal instead of writing. ? Holding a book during reading time. ? Understanding the effect World War II has on the present rather than knowing the names and dates of key battles. c. Material or environmental adaptations. The material or environmental changes are utilized so that participation in the general education curriculum by the student with the IEP may occur. Examples include: ? 5 spelling words from the weekly list instead of the standard 20. ? Completing a cooking assignment by following picture directions rather than written directions ? Changing the grouping of the class from large group to small groups (possible with the additional support staff). ? Changing the instructional delivery from lecture to the cooperative learning format ? Using a computer to write an assignment instead of paper and pencil. ? Reading a test to a student. ? Highlighting the important concepts in a textbook. ? Having the student listen to a taped textbook. ? Using enlarged print ?

Using an assistive technology device

127 ? Using visual cues such as picture and/or word schedules for those who have difficulty staying on task. ? Using a note taking guide listing the key concepts during a lecture. d. Providing Physical assistance. Assistance from another person may be needed for a student to participate

in a

classroom activity. If possible, it is better to use natural supports (peers) as these will be the people always present in the student's life. If the use of peers is not possible, then either the support teacher, the paraprofessional, the classroom teacher, the classroom aide, or a parent volunteer may provide the assistance. Most peers and staff will need training in the correct way of providing physical assistance. In addition, we need to keep in mind the principle of partial participations. Examples include: ? Starting a computer for an student with an IEP (Individualized Educational Programme) to use. ? Guiding a hand during handwriting. ? Assisting in activating a switch. ? Completing most of the steps of an activity and having a student with an IEP do the remainder. ? Pushing a student in a wheelchair to the next activity. e. Alternative/substitute curriculum. This is sometimes referred to as functional curriculum as it usually involves the acquisition of "life skills." The decision to use alternative/substitute curriculum is a major change and needs to be reflected on the IEP. This decision should be carefully made after weighing all

of

the pros and cons of using an alternative curriculum. The alternative curriculum may or may not take place in the general education classroom. Examples include: ? Community-based instruction (which all students may benefit from!) ? Learning job skills in the school cafeteria. ? Learning how to use a communication device.

128 ? Doing laundry for the athletic department ? Learning cooking/grooming skills at the home. 4.5

Adapting curriculum-content, teaching learning material, and instructions. Adaptation of Curriculum We already know that

curriculum has a broad range of experiences. It is the totality of all teaching learning experiences provided to a child inside and outside the classroom for bringing about the desired results.

Hence curriculum adaptation would include adaptation in: 1. syllabus, methods and techniques of teaching. 2. co-curricular activities. 3. evaluation procedure. 4. teaching learning materials. All the above would have to be adapted differently at different levels i.e., preschool, primary and secondary.

1. Adaptation of Syllabus, Teaching Methods and Techniques
The special school for children with hearing impairment is planned for duration of four to five years. This is so as to develop the natural language base required for primary education. However the duration depends upon the language level. It may even be curtailed if the child's achieves age appropriate language and communication skills. The teacher student ratio of 1:4 or 5 is maintained in pre-schools. Similar to regular schools, a special curriculum for the hearing impaired is prepared by the respective schools taking into consideration the children's needs and social and cultural background. It is especially aimed at developing functional language so as to facilitate the development of communication skills. Activities are specially contrived to develop receptive and expressive language. Various special methods like natural, structural and maternal reflective method are also used to teach language.

Variety of

techniques like show and tell, news conversation, storytelling, directed activity, visits; poems etc.

are used to

129 enhance language learning. Rigorous drill work is done through play way method.

Calendar activities, mathematical skills, environmental studies and physical activities are included to provide language rich experience. Adaptation in these includes changes like teaching mathematical concepts through word problems and emphasizing the verbs and question forms in the language classes. Along with language, listening and speech skills are developed through auditory training. Speech reading is also fostered. Different techniques are used for the development of reading skills. The 'Whole word method' is used for teaching reading along with phonic method. The entire learning is based on the experiences of the children. Parents are also empowered to become equal partners in the educational process because much of the language learning experiences are experienced at home. Adapting the resources Resource materials are not just the text books, but also those materials, which the teacher selects for instructing the students. Adapting resources is considered to be one of the areas which require improvement. Resource materials include texts, worksheets, exercises, black board notes, and computer software. Some strategies given by James and Brown (1998) Squires (2001) which can be employed for modification of resource materials which are as follows:

Simplify the language (use short sentences, substitute simple words for difficult terms) Pre-teach any new vocabulary (if a difficult word cannot be simplified, ensure that it is looked at and discussed before students are expected to read it unaided) Provide clear illustrations or diagrams Improve legibility of print and layout Remove unnecessary detail Present information in small blocks of text, rather than dense paragraphs. Use bullet points and lists, rather than paragraphs where possible

130 make printed instructions or questions clear and simple Use cues or prompts where responses are required from the students (e.g. provide the initial letter of the answer, or use dashes to show the number of words required in the answer).

Adapting the text books Text book is an important resource material and is central to the whole teaching learning process. It is always a guide for the teacher and a uniting factor in language learning of a wide area. It is unquestionably the most widely used instructional tool. According to Hummel (1998) text books constitute the primary vehicle for delivering content knowledge and for determining in large measure what goes in a class. Access to text books is a significant factor in predicting academic Achievement (Heyneman et. al 1998) text books is a I .11 1998) Textbooks are thus a significant aspect of the educative process as necessary as the classroom itself, as indispensable as the classroom teacher. Textbooks have been commonly developed for all children. In some of the western countries a choice exists for selection of textbooks according to the reading level of the child. Such a kind of facility is not available in India and all children special or reading deficits follow the same text books. A study conducted by Wadekar and Mathew (2002) reveals that the special teachers of children with hearing impairment opine that the textbooks followed for children with hearing impairment are actually written for typical children and so the hearing impaired find it difficult to comprehend the textual language or content. Teachers strongly recommended for developing adapted textbook for instructional purpose and for self learning. One of the observations of the teachers is that the text books language is too complex and differs from everyday language of the hearing impaired. Usually the textbook

language is attuned to the Language of the hearing, children. Too many concepts are presented together.

The presentation does not facilitate conceptual clarity among children with hearing impairment, because of the following: Vocabulary

load. Complex and long sentence structure.

131 Use of too many abstract word. Usage of idiomatic language. Wadekar and Mathew (2002) opine that due to the above mentioned factors, children with hearing impairment show less interest in using the textbooks rather they refrain from using these. Children try to pronounce the words without understanding the meaning, and use superficial visual matching while answering the question. However problems like unfamiliar vocabulary, idioms and phrases, and specialized vocabulary are some of the problems faced by normal hearing children also. Adaptation of the material could overcome some of these problems. Adaptation is not reducing or changing the content, but the thrust is on the simplicity for knowledge acquisition some strategies suggested can be the following. Simple meaning, to the new vocabulary can be provided. Complex sentences can be made into simpler ones. Abstract words can be explained with illustration. For idiomatic expression suitable explanation has to be given. If the adaptation is minimum it can be done on the existing material itself. If required, additional booklets can be used to supplement the textbook. Adapting the approach Since children with hearing impairment have problem with understanding and expressing their needs through language, there is a need to improvise the approach to teach them. Given below are some approaches that are suitable to teaching children with hearing impairment As per the convenience of the particular child, a teacher has to adapt the approach to communicate effectively to the child. Children with hearing impairment can be taught to understand what has been communicated to the end respond appropriately through different ways like. Verbal or oral-aural approach When a child is taught to communicate using speech, it is known as the verbal approach. In the verbal approach both the sender of the message as well as the receiver of the

132 message would use speech for communication. There are several advantages of teaching speech to a child with hearing impairment. The advantage of communicating through speech is that they adjust more easily to their surroundings, throughout their life, thus improving the quality of their life. When a child uses the verbal mode for communication, he/she can study more easily in an inclusive set-up, thereby widening the vocational options. The Pasco can participate I utilize the information I entertainment provisions available in the society. Hence the child will have less psychological stress. However, while using this approach to teach. The teacher has to be careful to use clear speech, short sentences, well-timed pitch and slow pace of speech. It is also necessary to make the children with hearing impairment position in such a way that they get a clear view of the teacher to facilitate better reception of speech. It is essential to make the children seated away from. The source of noise. If any in the vicinity of the class to avoid auditory distraction. Non-verbal approaches - Non-verbal approaches include any method where the individual with communication disorder tries to communicate without using speech. The most common among nonverbal method is communicating with hand shapes and movements. When, a person uses his/her hands in a specific and systematic way to communicate, it is known as manual form of communication. There are different ways in which the manual form of communication can take place. Some of them are finger spelling and sign language. Children who use the manual method communicate comprehend better even if there is no useful residual hearing. The person can learn easily and faster than speech and as a result psychological stress is less. To use these approach in teaching process, the teacher has to be well versed with it the care has to be taken to see that the sign used by the teacher means the same to the students. since the written form of communication use verbal language there is additional burden for children to learn that also because writing is mandatory in our education system. Combined approach Sometimes children with communication disorders are helped to learn and use both verbal and manual methods. Combining the two approaches may help them to learn to

133 communicate easier and better. Some of the examples of combined approach are cued speech and total communication. Depending on the situation, the teacher has to make use of the communication approaches. The main idea is that the child comprehends the lesson. While adapting the material, the approach that may be used to communicate the same may also be decided. In our classrooms most of the times, total communication is used to reach children with hearing impairment. Adaptations in methods Different methods of teaching are used to teach typically developing children in the classroom: However, while teaching children with hearing impairment, the same methods could be used, but it has to be modified according to the needs of the children with hearing impairment. Below given are some methods that can be improvised to suit children hearing impairment. Project method Project method applies the principle of learning with through planning which requires total involvement of the children. Children with hearing impairment learn better when they are involved in the teaching learning process and when they become a part of it. So, teachers can make use of the project method so that children become actively involved in teaching learning process. Project method aims at providing community life activities on small-scale in the school. The project-method is the outcome of the pragmatic educational philosophy of John Dewey, the noted American philosopher-cum-educator. The pragmatic educational philosophy lays great stress on providing different kinds of rich experiences to children. The project method is the expression of the wide spread dissatisfaction against the bookish, encyclopedic method which makes children passive and in which children are drilled and spoon-fed with information which mostly is unconnected with real life situations. Activity method There is no doubt that given the chance children with hearing impairment can achieve

134 better when curriculum materials emphasize active learning and hands on activities. Children learn enthusiastically and quickly, when they are actively involved in the teaching-learning process. The biological science curriculum study (BSCS) has developed materials characterized by low verbal content, and an emphasis on hands on activities, The study resulted in substantial gains and retention of the content for children with hearing impairment who participated in the study.(Grant et al., 1975). In activity method a person engages in an activity in which they are free to do what they want. They learn through their mistakes, as they are sure to make errors in their freedom to explore the situation, There is ample opportunity given to the child for self-expression. Heuristic method The word 'Heuristic' is derived from a Greek word 'heuriskein' which means 'I discover' or 'I find'. Hence the heuristic method is the method in which children discover and find things for themselves and are placed in the position of discoveries or inventors. This method was first used by Prof. Henry Edward Armstrong of the Imperial College London in the teaching of science. Prof Armstrong involved his students in finding out by themselves instead of telling or lecturing them. Laboratory work was compulsory for every student where he could discover instead of being told. The main objective of the heuristic method is "to make pupils more exact, more truthful observant, thoughtful and dexterous to lay the solid foundation for future self-education and to encourage the growth of a spirit of enquiry and research. School subjects could be made interesting if the right kind of method and technique is employed. A child with hearing impairment learns better when different senses are involved in the learning process. When a child with hearing impairment is allowed to touch, feel, see, hear and manipulate, he learns better. The same principle is utilized by the heuristic methods wherein children learn by themselves by discovering it. Guidance of teacher at every stage is essential. Depending on the content, suitable method can be adapted. The teacher has to be creative to adapt the material, approach and method as per the situational demand. Though this seems laborious initially, as the benefits are multifold, teachers will be motivated to - use improvised techniques in their day today classes.

135 2. Adaptation

of Co curricular Activities In special preschool curriculum the drawing and craftwork are considered as supplementary for language learning.

Every subject and every lesson in a preschool programme becomes a language-learning lesson. Hence celebration of functions and festivals are included not only for social purposes but also for

providing language learning experiences. Competitions are also organized with a dual purpose. First, to develop competitive spirit and secondly to provide an experience to learn language.

E.g. through fancy dress competition of community helpers teachers increase the general knowledge about the community helpers and also encourage communication through interaction. 3. Adaptation of Evaluation The assessments are a continuous activity conducted both, individually and in group in the preschool curriculum. The children are assessed prior to teaching in order to know their language and knowledge levels. These are need used to plan the objectives, lessons and while deciding the teaching strategies.

Various standardized tests and teacher made tests are used for assessing the development of linguistic, conceptual and literacy skills in the children with hearing impairment.

In a special preschool curriculum assessment of both language and knowledge are given equal importance.

Need based adapted worksheets are prepared by the teacher for evaluation. Depending upon the levels, teachers may give clues in brackets, use pictures in the sheets, or give different kinds of puzzles etc.

Auditory skills and speech skills are also evaluated

for setting the teaching goals. 4. Adaptation of Teaching Learning Materials Amplification devices have to be installed in a preschool class.

Induction loop system, Frequency Modulated hearing aids are more suitable at preschool level as they do not obstruct the mobility of the children and provide flexibility to both the teachers and the preschoolers. Lot of teaching learning material are required while teaching the children with hearing impaired at pre-school. Flash cards, charts, models etc. are extensively used, Storybooks' scrapbooks for conversations, teacher made reading materials are also prepared. Sometimes experiences are enriched through real objects.

For this a variety

136 of material is

used like pieces of different types of cloth, feathers, stones, sand pebbles, etc.

Though globes, weather cock, maps are not required for the curricular subjects; these teaching aids are also sometimes used by the teachers for developing concepts while undertaking news conversations in the preschool class. The various adaptations done for the children with hearing impairment in the curricular transactions have been discussed. All these are done with an aim of to facilitating language development. The set goals of special education can be achieved only if these adaptations are implemented properly. This is possible when an appropriate infrastructure is made available and the activities are scheduled properly. Therefore certain adaptations have to be made in the environment to make it learner friendly. So adaptations are required in the infrastructure and time-table for the children with hearing impairment. Since opportunities for learning especially for language development have to be 'seized', adaptation in the time-table are also very essential. (a) Adaptation

of Classroom Infrastructure and Arrangement: Adaptation of infrastructure has to be made in terms of arrangement

of light, furniture including blackboard, level of teacher's chair etc.

This is done to facilitate good listening and speech reading. The walls and floor is also adapted considering the acoustic features to reduce noise.

The arrangement of a preschool is flexible as the small children have to undertake various activities. Group activities are conducted in a semicircular seating arrangement to facilitate communication skills. While as for other activities like free play, individualized teaching, reading' speech teaching the arrangement can be different.

Sometimes speech booth with mirrors are also created in the class. (b) Adaptation of Schedule:

The time-table at preschool level is very flexible. The duration of each period is also flexible.

the techniques used for teaching language like directed activity, story visits usually find a place in timetable itself .Also ,auditory training ,speech teaching and reading are also include in the time table .though there may be an allocated slot for news conversation,this slot also get adjusted according to the seized opportunity

137 for news conversation.Ususally

the morning hours are allocated for the teaching of new things and later hours for the drill work, The recess time is also utilized for providing

teaching learning experiences and language learning experience by either the teachers, or voluntary workers or teacher assistants. Adaptations at Primary and Secondary Level 1. Adaptation of Syllabus, Teaching Methods and Techniques

The syllabus at these levels is similar to that of the regular schools. However only one language is compulsory.

The activities of news conversation,

auditory and speech training are still continued at least during the list levels. However as the children progress towards secondary level, emphasis on these activities is gradually reduced.

At the secondary level the syllabus is similar to that of the regular schools but only one language is compulsory. There is flexibility to choose either higher or lower level of this language. Various vocational subjects are offered in place of the other two languages. In some state educational boards, children are given choice of lower Maths (Maths of Std. 7th) instead of algebra and geometry.

Instead of science they can opt for Home science (Physiology and Hygiene). Special vocational training subjects are also included in some educational boards. Work experience is included in the syllabus of some educational boards too. Since the Preschool 'focuses on language development, at the primary and secondary level along with language, subject teaching is also emphasized. Reading lessons are geared towards development of independent reading skills take an important position.

Development of mathematical language is emphasized for solving word problems and other equations through mathematics. Various methods like project method, demonstration method, heuristic method, lecture method are also used in an adapted form. While teaching from textbooks, different techniques of teaching like narration, questioning, and dramatization are used instead of the routine Listening, Reading and Speaking Method (LRS Method).

138 Many a times children are group as for auditory training and speech teaching. Gestures and finger spellings (if required) are also incorporated while teaching the primary and secondary

children. Art and craft subjects are again supplementary lessons for language development. Physical education is also used for development of auditory skills and language.

Various activities to develop observation skills, communication skills are included along with the regular school subjects. Rigorous drill work is done through follow-ups. 2. Adaptation of Co-curricular Activities All co-curricular activities are geared towards language develop-ment. Festivals and competition are conducted with dual purpose of language teaching and socialization.

Outdoor sports are also conducted and these experiences are used for developing interaction and communication.

Girl guides, hiking and excursion are taken for promoting social integration. Inter and Infra School (both special and regular schools) competitions are specially undertaken to

facilitate mainstreaming. Prevocational skills are developed through activities likes fabric painting, book binding, screen printing, computer training etc.

in these sections. 3. Adaptation of Evaluation Strategies Continuous and ongoing evaluations is a regular feature of special education at all levels. Every topic ends with an evaluation. Due to problems in understanding of language and difficulties in reading, sometimes less weightage is given to inferential type of questions in the evaluation. While evaluating the children .with hearing impairment equal weightage is given to knowledge and language assessment. Auditory and speech skills are also evaluated to plan further strategies of teaching. At the secondary level, marks assigned may vary depending upon the subjects opted. Marks of some subjects like lower maths, home science are combined with vocational subjects. Extra half an hour is given to the students for the exams if required. Adaptations in the infrastructure and schedule are also required at the primary and secondary level also for successful implementation of the - adapted curricula.

139 4. Adaptation in Teaching Learning material Group amplification devices are installed in the classroom. Teaching aids like charts, models are extensively used. These days even Computer Assisted Instructions are given to the children in special schools. Considering the problems of language and reading, textbooks used for the special children are adapted so that the children understand the concepts through reading.

While adapting the textbooks, the language is made simple, concepts are made clear through simple presentation and extra examples, illustrations are also added and the presentation of matter is made simple through use

of bullets forms, tree diagrams, pie-diagrams etc. (a) Adaptation in Classroom Arrangement and Infrastructure:

The seating arrangement in the primary and secondary sections of the students is semicircular or U shaped and is usually fixed.

Group hearing aids are installed. Folding blackboards with provision of graphs are also used. Soft boards are placed near the blackboards to pin charts etc.

Arrangement of lights in the class is also adapted. Assistive listening devices like glowing lights instead of bells etc. are also some of the adopted features.

Acoustical treatment is given to the walls and floor to reduce noise levels. Classrooms have different corners for individual and group teaching and other pre-vocational activities. (b) Adaptation of Time-Table: Auditory training and speech training have a place in the time-table along with other subjects. Distribution of hours is need based. More hours are allocated for language. Co-curricular activities also have place in the time-table. Adaptations in Continual Education : The avenue of open education though distance mode is also available to the children with hearing impairment. This programme has flexibility in terms of age, time, choice of subjects and evaluation. Adaptation is done in terms of Special Accredited Institutions setting up to provide barrier free environment to the disabled students. Though the syllabus and subjects remain the same as students with normal hearing, the number of hours of contact programme, the methods and techniques of teaching during the contact sessions is adapted for the children with disabilities.

140 4.6 Types of adaptation and process.

Nine Types of Adaptations

Size

Adapt

the number of items that the learner is expected to learner compete.

For example: Reduce the number of social studies terms a learner must learn at any one time.

Time Adapt the time allotted and allowed for learning, task completion or testing. For example: Individualize a timeline for completing a task;

pace learning differently (increase or decrease) for some learners.

Input Adapt

the

way instruction is delivered to the learner. For example:

Use different visual aids; plan

more concrete examples; provide hands-on activities; place students in cooperative groups.

Difficulty

Adapt

the skill level, problem type, or the rules on how the learner may approach the work. For example: Allow a calculator for

math problems; simplify task directions; change rules to accommodate learner needs.

Degree of

Participation Adapt the extent to which a learner is actively involved in the task.

141 For example: In geography, have a student hold the globe, while others point out the locations.

Alternate Goals Adapt the goals or outcome expectations while using the same materials.

For example: In social studies, expect one student to be able to locate just the states while others learn to locate capitals as well.

Level of Support Increase the amount of personal assistance with specific learner.

For example: Assign peer buddies, teaching assistants, peer tutors.

Output Adapt how the learner can respond to instruction For example: Allow a verbal vs. written

response; use a communication book for students; allow students to show knowledge with hands-on materials.

Substitute Curriculum Provide the

different instruction and materials to meet a learner's individual goals.

For example: Individualize a timeline for completing a task; pace learning differently (increase or decrease) for some learners.

For adapting curriculum successfully an educator should follow the process-

Step 1. Create a Plan for Adapting Materials Effective adaptations require sustained development and support. They must be made

142 within the framework of a larger plan that includes consideration of (a) basic and strategic skills instruction and (b) the roles of people involved in the adaptation process. In some cases, it is important to involve your administrator and curriculum or program coordinator from the beginning, and identify exactly who will be responsible for making, implementing, supporting and evaluating the adaptation over the course of the year. As much as possible, involve students, parents, paraprofessionals, and others. Adaptations that can benefit an entire class or several classes are more likely to be supported and maintained. Step 2. Identify and Evaluate the Demands that Students Are Not Meeting The purpose of this step is to define the problem to be addressed by the adaptation. Observe students' performance when they use typical instructional materials. They may have difficulty acquiring or getting the important information from written materials, storing or remembering the information presented in the materials, or expressing the information or demonstrating competence on written tests. If students have difficulty with a given task, different solutions may be required depending on the level of difficulty and the student's individual needs. Step 3. Develop Goals for Teaching Strategies and Making Adaptations Some problems can be solved by adaptations; other problems may signal the need for intensive instruction in skills or strategies. Often, teachers may need to provide adaptations while simultaneously teaching the student the learning strategies he or she needs in order to perform the work. All adaptations lead students to become dependent on the person who makes them. Before an adaptation is made for an individual student, educators must carefully consider the best approach to addressing the student's difficulty and promoting success. Adaptations should be approached as short-term solutions within a long-term plan for teaching skills and strategies that will promote the student's independence as a learner and ultimately reduce the need for adaptations. Step 4. Determine Whether Content or Format Adaptations Are Needed Content adaptations may be made only when the student's Individualized Educational Program (IEP) notes that the general curriculum is inappropriate for this student. Content adaptations must also meet local and state education standards. In some cases, the IEP may address the degree to which the requirements associated with meeting state standards and taking assessments may be modified. The teacher must decide which parts of the curriculum the student will be required to learn and will constitute mastery of the course content. When the curriculum is considered appropriate for the student, adaptations may focus on format rather than content. Again, the teacher must identify the critical elements of course content that students must learn: First, identify the critical course ideas or concepts. Then identify the information that must be mastered in each unit to ensure that the critical course ideas are mastered. Finally, determine how students will demonstrate their mastery at the end of each unit and at the end of the course. Format adaptations are made to compensate for mismatches between the presentation or design of the materials and the skills and strategies of the student. In format adaptations, the content is not altered. Step 5. Identify the Features of the Materials that Need To Be Adapted The design of materials can present many different types of problems for students who struggle. Teachers adapting materials should examine each curricular unit for features that might cause a learning problem. For example, the content may be very abstract, complex, or poorly organized, or it might present too much information. It may not be relevant to students or it may be boring. Further, it may call for skills or strategies or background information that the student does not possess. It may present activities that do not lead to mastery, or it may fail to give students cues about how to think about or study the information. Materials also may not provide a variety of flexible options through which students can demonstrate competence. Guidelines for identifying these and other problems in the design of instructional materials may be found in resources like those listed at the end of this article. Step 6. Determine the Type of Adaptation That Will Enable the Student To Meet the Demand Once the materials have been evaluated and possible problem areas identified, the type

144 of format adaptation must be selected. Format adaptations can be made by Altering existing materials-Rewrite, reorganize, add to, or recast the information so that the student can access the regular curriculum material independently, e.g., prepare a study guide and audiotape. Mediating existing materials-provide additional instructional support, guidance, and direction to the student in the use of the materials. Alter your instruction to mediate the barriers presented by the materials so that you directly lead the student to interact with the materials in different ways. For example, have students survey the reading material, collaboratively preview the text, and create an outline of the material to use as a study guide. Selecting alternate materials-Select new materials that are more sensitive to the needs of students with disabilities or are inherently designed to compensate for learning problems. For example, use an interactive computer program that cues critical ideas, reads text, inserts graphic organizers, defines and illustrates words, presents and reinforces learning in smaller increments, and provides more opportunities for practice and cumulative review. Step 7. Inform Students and Parents About the Adaptation Adaptations are more successful when they are offered and introduced to students at the beginning of the year. Parents should also be informed about them at the beginning of the year. Students should be taught clear strategies to use any adaptation effectively and how to process the information received through the adaptation. As students' progress, they should be taught how to recognize the need for and request materials adaptations. Step 8. Implement, Evaluate, and Adjust the Adaptation As the adaptation is implemented, the teacher should evaluate its effects to determine whether the desired outcomes are being achieved. If not, adjustments will need to be made either in the adaptation or the instructions to the student in its use. Adaptations should significantly reduce failure and learning difficulties. Step 9. Fade the Adaptation When Possible Adaptations usually are short-term solutions to allow classroom learning and participation

145 until the needed skills and strategies can be taught. Once the adaptation is in place, the teacher should begin to plan with other teachers how to teach the needed skills and strategies. Once the student has learned the necessary skills and strategies, the adaptation should be faded. The adaptation should not be removed until the student possesses the skills and strategies to learn and complete tasks independently. For some students, an adaptation may be required for several months, while for others; it may be maintained for years. 4.7

Adaptations and accommodations in students evaluation and examinations. Accomodations are not the same as instructional interventions for student with hearing impairment. It helps hearing impairment students access information and show what they know and are able to do and who are unable to achieve grade-level benchmarks due to a significant disability and may learn alternate achievement standards about the next generation. Continuous and ongoing evaluations is a regular feature of special education at all levels. Every topic ends with an evaluation. Due to problems in understanding of language and difficulties in reading, sometimes less weightage is given to inferential type of questions in the evaluation. While evaluating the children .with hearing impairment equal weightage is given to knowledge and language assessment. Auditory and speech skills are also evaluated to plan further strategies of teaching. At the secondary level, marks assigned may vary depending upon the subjects opted. Marks of some subjects like lower maths, home science are combined with vocational subjects. Extra half an hour is given to the students for the exams if required. Adaptations in the infrastructure and schedule are also required at the primary and secondary level also for successful implementation of the - adapted curricula.

146 ? Use peer tutor, paraprofessional, or volunteer to work with student to review for test. ? Allow test items to be signed to the student and the student to respond in sign. ? Allow tests to be taken with teacher or paraprofessional who works with students who are deaf or hard of hearing. ? Provide extra time to complete tests and quizzes. ? Allow test items to be read to the student. ? Modify vocabulary used in test items to match student abilities. ? Modify the number of test items. ? Provide short tests on a more frequent basis. ? Chart progress or lack of progress. ? Provide additional information to explain test questions and instructions. ? Allow student to use notes/study guide/textbook on tests. ? Evaluate daily work/participation in addition to tests. ? Use projects or portfolios in lieu of tests. ? Provide graphic cues (e.g., arrows, stop signs) on answer forms. ? Give alternative forms of the test (e.g., matching, multiple choice questions, fill in the blank, true/false questions, short answer questions, essay questions). ? Teach test-taking skills. 4.8

Let us sum up In this unit we have discussed about the Meaning and Principles of curricular adaptation. We have also discussed about the necessary assessment and decision making for curricular adaptation. We came to know about the areas where adaptation is done. We

147 discussed different types and process of adaptation .The unit ends with the discussion on the adaptation and accommodations in Student's Evaluation and Examinations 4.9

Explain Different types of

Methods and Tools for Curricular Evaluation ? Discuss recent trend and Challenges in Curricular Evaluation 5.3 Concept Need for Curricular Evaluation

What is the curriculum? Curriculum is a set of planned and purposeful learning experiences, based on intended learning outcomes and organized around the developmental levels of students. It can take many forms according to the viewpoints from which it is approached. Tyler (1949) quoted in Kelly suggested that the curriculum has to be seen as consisting of four elements: objectives, content, methods and evaluation. He seeks to answer the four fundamental questions in developing any curriculum: 1.

What educational purposes should the school seeks to attain? 2. What educational experiences can be provided that is likely to attain these purposes? 3. How can these educational experiences be effectively organized? 4. How can we determine whether these purposes are being attained?

These four questions can be viewed as the four main elements in the Curriculum Development Process. As can be seen in Tyler's last question and the model of the Curriculum Development Process, curriculum evaluation is an integral part of curriculum development. Curriculum evaluation is used not only to determine the attainment of the purposes but also "to gauge the value and effectiveness of any

151 particular piece of educational activity - whether national project or any particular piece of work undertaken with our own pupils" (Kelly 1989, p. 187). Curricular evaluation means rendering value judgment to a set of experiences selected for educational purposes. It is a process that involves gathering information about the effectiveness of Curricular and measurement is done in terms of levels of achievement of the pre-set objectives. Among the many reasons for undertaking Curriculum evaluation we have the following: To allow the curriculum developers and implementers be certain about the functions of the curriculum put in place (feedback) It also gives information on the relevancy of the curriculum in the society. Information on the effectiveness of the instructional materials is obtained through evaluation. Curriculum evaluation is a necessary and important aspect of any national education system. It provides the basis for curriculum policy decisions, for feedback on continuous curriculum adjustments and processes of curriculum implementation. The fundamental concerns of curriculum evaluation relate to: Effectiveness and efficiency of translating government education policy into educational practice; Status of curriculum contents and practices in the contexts of global, national and local concerns; The achievement of the goals and aims of educational programmes. 5.4

Factors associated with curricular evaluation (learner, content, instructor and resources)

Learner The ultimate goal of curriculum evaluation is to ensure that the curriculum is effective in promoting improved quality of student learning. Student assessment therefore

152 connotes assessment of student learning. Assessment of student learning has always been a powerful influence on how and what teachers teach and is thus an important source of feedback on the appropriateness implementation of curriculum content. Fulfilling the diverse objectives of diagnosis, certification and accountability requires different kinds of assessment instruments and strategies selected to achieve specific purposes. Assessment of student learning could be summative or formative, and there are various types of tests to address different needs such as standardized tests, performance-based tests, ability tests, aptitude tests and intelligence tests.

Curricular Content The goals of education reflect perceived needs and expectations of society. Curriculum decisions are made within the context of these goals. It is important that goals determine content. Allowances must be made for variations in curriculum content to reflect the unique needs of communities in general and of students in particular. Thus a close association among those who set goals, create content and implement curriculum is essential. Goals for education include possession of respect for self and others, a sense of social responsibility, feelings of self worth and integrity, and the knowledge, skills (including ethical and living skills) and attitudes required in a democratic society. The basics in education are those learning experiences that assist students in acquiring knowledge, skills and attitudes that contribute to continued learning, social awareness, and cognizance of a changing society, responsible citizenship and personal well being.

Instructor The Code of Professional Conduct and the Declaration of Rights and Responsibilities for Teachers identify members of the teaching profession as major advocates for the educational welfare of students. Because it is teachers who must translate curriculum into specific learning experiences, teachers must be central figures in curriculum decision making. Decisions concerning objectives, content, interaction and student evaluation must be made by sources as close to the students as possible. Classroom

153 teachers are also in the best position to develop evaluation strategies that align with the curriculum and address the individual learning needs of students. It is a teacher's role to facilitate learning experiences of students. Efficient expedition of this role requires the provision by school jurisdictions of adequate time and resources to translate the aims and objectives of curriculum into learning activities that will meet the needs, motivation and capabilities of students. Professional education and teaching experience prepare teachers well for having a major voice at all levels of curriculum decision making.

Curriculum evaluation involves, Intra-curricular evaluation, Teacher evaluation of students, Student evaluation of teachers, Materials evaluation, Verification of methods, Evaluation of tests and improvement/ change/ modification, System revision. Curriculum development phases consist of Instructional development, Materials & media development, Methods of teaching & testing. Implementation of the Curriculum involves Instructional scheme of each subject to be completed in the semester, Planning the lessons as per the timetable, Using the transactional strategies, Using the appropriate media, Providing the learning resources, Promoting classroom learning experiences, Progressive testing. After evaluating the prepared curriculum it is observed that the curriculum is not satisfactory then developer turns for revising and improving phase.

Curriculum Support Even with good curriculum content and processes in place, attention needs to be given to mechanisms that will support curriculum. Without adequate funding and resources, the best curriculum becomes difficult to implement. Implementation of a new curriculum requires that draft program and resources are evaluated through a pilot project, approved programs and resources are available at least eight months prior to implementation and sufficient funding is available for teacher inservice and purchase of approved resources. An important support mechanism to the delivery of curriculum is the provision of library services via libraries and qualified teacher librarians; these services can bolster all levels of instruction. In meeting needs of students, considerable attention must be given to those students with special needs. While this may be done via special programs and courses to meet a wide range of talent and ability, there is an obligation for society to provide the

154 education system with the resources to identify those with special needs and, where required, provide professional assistance to design and offer special programs.

Relationship Between Curriculum, Student Assessment and Evaluation Student assessment and evaluation are an integral part of curriculum development. Teachers understand the complexity of curriculum which in Alberta is expressed in the form of learning outcomes. They further recognize that many learning outcomes cannot be measured using the traditional pencil-and-paper techniques. As such, students must be assessed and evaluated on the curriculum they have been taught. Classroom teachers design student evaluation based on the curriculum that students have been taught. It is unfair and unethical for teachers to evaluate students on material they have not had the opportunity to learn.

5.5 Areas of Curricular Evaluation : Context, Input, Process and Product. The CIPP Evaluation Model

One very useful approach to educational evaluation is known as the CIPP, or Context, Input, Process, Product approach, developed by Stufflebeam (1983). This provides a systematic way of looking at many different aspects of the curriculum development process. There is a risk, however, that it may be directed only by experts or outsiders, and for this reason it is vital to identify ways in which various stakeholders can be meaningfully involved.

CIPP Model Use for Curriculum Use for Curriculum Component Development Evaluation

Context To define the operating environment context within which the relevant to the curriculum, curriculum will be delivered. describing the actual and Determine the specific intended conditions of the characteristics of the learners. program, identifying unmet Most importantly, it helps to needs, and diagnosing barriers establish a rationale for the that prevent needs from determination of the being met. curriculum objectives.

155 CIPP Model Use for Curriculum Use for Curriculum Component Development Evaluation Input To identify and assess the To determine to what extent capabilities, strategies, and available resources were used designs available for to achieve the curriculum implementing the curriculum objectives. as related to the curriculum's objectives. Determine what internal resources are needed to enable achievement of the objectives and to search for external resources when required. Also, the input phase considers the cost to implement the curriculum. Process To identify the procedural To identify deficiencies design that will be used to in the procedural design implement the curriculum. or in the implementation The curriculum objectives of the curriculum, i.e., are translated in specific what actually took place activities that constitute during instruction. To the instructional design. provide information necessary to make modifications to the implementation strategies used during instruction. To maintain procedural documentation. Products To define the measurable To compare actual outcomes outcomes of the curriculum against a standard of what is both during and at the acceptable to make judgments completion of instruction. to continue, terminate, modify, These outcomes are directly or refocus an activity. related to the curriculum objectives.

156 Context evaluation Objective: To determine the operating context To identify and assess needs and opportunities in the context To diagnose problems underlying the needs and opportunities Method: By comparing the actual and the intended inputs and outputs Relation to decision making: For deciding upon settings to be served For changes needed in planning Input Evaluation Objective: To identify and assess system capabilities, available input strategies and designs for implementing the strategies Method: Analyzing resources, solution strategies, procedural designs for relevance, feasibility and economy. Relation to decision making: For selecting sources of support solution strategies and procedural designs for structure changing activities. Entry behavior of students Curriculum Objectives Detailed contents Methods and media Competencies of teaching faculty Appropriateness of teaching / learning resources

157 Process evaluation Objectives: To identify process defects in the procedural design or its implementation Method: By monitoring the procedural barriers and remaining alert to unanticipated ones and describing the actual process. Relation to decision making: For implanting and refining the programme design and procedure for effective process control. Feedback to judge The effectiveness of teaching –learning methods Utilization of physical facilities Utilization of teaching learning process Effectiveness of system of evaluation of students performance Product evaluation: Objectives: To relate outcome information to objectives and to context input and process information Method: Measurement Vs Standards interpreting the outcome Relation to decision making: For deciding to continue, terminate, modify, build or refocus a change of activity. 5.6 Methods and tools for curricular evaluation. Action Research: Why Do We Promote School-based Curriculum Action Research? Collaborative school-based curriculum action research aims to : enable teachers to enhance quality learning and teaching through knowledge

158 generated and constructed in the process of critical and systematic inquiry into different learning and teaching issues; develop teachers' competence in curriculum development and research literacy as well as their sense of curriculum ownership; and develop schools into learning organizations through collaborative team work within schools and professional sharing in school networks. How Do We Conduct Collaborative School-based Curriculum Action Research? In the course of school-based curriculum development, teachers' critical reflections will help them identify issues worth addressing in the form of an action research. The following steps illustrate the basic cycle in action research : 1. Examine critically learning- or teaching-related issues worth researching into. 2. Define the research focus and review literature for current theories and practice. 3. Develop action plans or intervention strategies. 4. Implement action plans in contexts. 5. Collect evidence and reflect on effectiveness of actions. 6. Draw conclusions and use feedback to improve learning and teaching. 7. Start a new cycle if necessary. As teachers progress through this spiral cycle, they improve their teaching through continual reflection and move closer to the solution of the identified problems. Taking the role as facilitator, Curriculum Officers from the SBCD(P) Section work as partners with teachers, rendering professional support throughout the research cycle, assisting them in reflecting and conceptualizing tacit knowledge embedded in their practice. How Can These Reports Be Used? This series of action research reports portrays the participating teachers educational beliefs and philosophy, and the developmental pathway undertaken to improve the school curriculum. The curriculum design, intervention strategies, action plans, research tools and instruments, as well as the findings and recommendations may be valuable references for teachers who intend to launch school-based curriculum development and/or collaborative action research in their schools. We sincerely hope that this series can serve as a platform to stimulate professional dialogue in curriculum research and development, and to spark off a research culture in primary schools in Hong Kong.

159 Student Feedback: When using student feedback to evaluate your curriculum it is important to be clear what kind of information you want and therefore how you elicit it. Methods of obtaining student feedback Methods of obtaining student feedback may be formal or informal, structured, semi- structured or unstructured. They include surveys, minute papers, focus groups and student consultations. Formal, structured student surveys etc. Teaching Evaluation for Development Service (TEDS) TEDS provides formal student surveys focused on teaching and unit. TEDS receives survey orders from individual staff and Department Administrators, creates the surveys, receives and processes the data and provides reports on the results to individuals and Department Heads. Method TEDS surveys are usually conducted towards the end of the semester, providing feedback on students' experience of teaching and learning in the unit as a whole. Early Feedback surveys can be conducted in weeks 2-4 of the semester, to provide formative feedback and enable teachers to respond to student needs as the teaching period unfolds. Documentation TEDS provides summary reports for all surveys with at least four responses. These reports include: a graphical and numerical summary of the distribution of student ratings for each question; the response rate, and the mean and variation (standard deviation) of student ratings for each question; copies of student responses to open ended questions; A Reflection Sheet for you to record your own reflections and responses to the results you have received. Reports and completed reflection sheets should be kept in your Academic Portfolio, as they provide evidence of your critical reflective practice in teaching.

160 Informal, semi-structured surveys Early Evaluation Early evaluation is useful in providing you with information on current student experience in your unit, especially if you are new to teaching. It gives you the opportunity to respond to issues identified by current students, engages students early with the feedback process, and also helps produce higher quality feedback at the end of the semester. Minute Paper or "3 Minute Evaluation" An excellent means of collecting information about your teaching during the semester is the Minute Paper or 3-minute evaluation. Method Ask the students to write comments about no more than two specific aspects of your class each week or two, and to leave the comments on a table as they leave the room. For instance: What are the best aspects of the teaching? What could the lecturer improve on? What was the most important thing you learned in class today? What do you still have questions about? An example of this type of informal, quick survey is provided in the Useful Links section below. From this form of feedback, it's easy to see areas in which you can make changes quickly (a request for sources of more information on a topic, for example, can simply be provided on an overhead the following week). Responding promptly to this type of feedback demonstrates to students that you care about the learning environment and their experience. If students raise issues that are not so easy to respond to quickly, you can still acknowledge their concerns and indicate your willingness to address them when time permits. You might also, if appropriate, take this opportunity to advise them about changing their own approach to learning in the unit.

161 Documentation Keep a record of Early Feedback Surveys and Minute Papers you've used, including your rationale for any optional questions you've chosen to include. Record and reflect on the feedback you receive and document your reflections and any action taken in response, in your Academic Portfolio. Follow this up by relating the results and your responses to the results of any later formal evaluation you undertake. Informal, unstructured feedback Method Ad hoc student consultations and discussions are an important source of informal feedback on how things are going in your unit. For this reason, in units with multiple teachers (lecturers and tutors) it's vitally important that the whole teaching team come together several times over the course of the teaching period to share information gained through this type of informal interaction with students. It is especially useful for a lecturer to hear from tutors about frequently asked questions, and aspects of the unit content or delivery that might be causing confusion or might be particularly challenging for some groups of students. Identifying these types of difficulties and challenges as the semester unfolds enables both lecturers and tutors to respond by focusing on those areas causing problems and by giving detailed feedback on relevant assessment tasks. This also provides an opportunity to follow up on the effectiveness of responses in a later, more formal evaluation . Documentation Note observations from teaching team meetings and your own informal interaction with students, and record your reflections on these and any actions taken in response, in your Academic Portfolio. Semi-formal, semi-structured student feedback Focus groups Focus groups are in-depth qualitative interviews conducted with a small group of carefully selected people, brought together to discuss a specific aspect of concern. Unlike the broad, one-way flow of information you receive from written evaluation instruments, focus groups provide a rich source of detailed information through the exchange of ideas and viewpoints from the group discussion. Focus groups allow a

162 more in-depth exploration of student experience and perspectives on a range of learning and teaching issues. Method Focus groups should be facilitated by an independent person unconnected with the teaching and assessment of the unit being evaluated. Their role is to develop a trusting relationship with the group, ask questions and elicit discussion. Decide on the aspects of curriculum on which you would like to obtain feedback, and the type of feedback you would find most useful. Discuss this with the focus group facilitator and together devise some questions to trigger group discussion. An experienced facilitator will be able to steer the discussion in the required direction, while maintaining an informal atmosphere and approach. The invitation to students to participate in a focus group should: clearly state the purpose of the focus group; include an assurance of anonymity of student responses; note that the focus group is to be conducted by an independent facilitator; and direct students to contact the facilitator to indicate their willingness to participate. Further, you should ensure that the timing of the focus group doesn't clash with times in which students will be preparing for major assessment tasks or examinations. It is appropriate to offer students some form of incentive for participation. If you would like to use the focus group method to obtain feedback on your unit, speak to your Department. Ideally, this should form a component of a planned cycle of unit evaluation, coordinated at Program or Department level, so that you would normally only conduct a focus group at most every three years in any one unit. Alternatively, focus groups are useful to run before and after a substantial change or development in curriculum (including changed mode of delivery), in order to accurately assess the impact of the change.

163 Documentation The focus group facilitator should provide you with a report including analysis of results and a summary of key points. If you have requested it, the report might also include recommendations for development. You should include key points from the report and record your reflections on this and any actions you take in response to its findings, in your Academic Portfolio. The Peer Review Process The purpose of peer reviewing our curriculum is to improve the quality of our work by strengthening our understanding of curriculum development, quality assessment, and effective instruction. Teams of teachers engage in a process during which a curriculum unit is analyzed to determine the extent to which it meets certain criteria. Adjustments are made to the unit based upon feedback from the team. Ideally, teachers from both within and outside the discipline or grade level participate in the peer review process. Thus, teachers gain a stronger perspective on the vertical and cross-disciplinary connections within our curriculum. Method Ask a trusted colleague (this might be your supervisor, mentor or one of your peers) to sit in on one of your face-to-face or online classes and provide you with feedback. Brief them in advance about the aspects of your teaching that you would like them to focus on. For instance, are you able to be heard clearly in the class? Are your explanations coherent? Do your slides communicate important ideas clearly? Do you need slides at all? Do your students seem involved in the class? Are the questions you ask and answer suitable? Below you will find links to some resources that may assist you and your colleagues with this process. Although much peer observation naturally focuses on classroom performance, there are many other aspects of teaching and the curriculum to which it can be applied. The scope of POT may therefore include but is not limited to: a review of learning and teaching materials and activities; assessment items; supervision; field work; classroom performance; learning outcomes; moderation of assessment; postgraduate supervision; online teaching; etc. A separate advice section on collegial review of curriculum and resources is included here, but really the advice is similar and any of the resources can be adapted and modified to suit.

164 Documentation Include your colleague's comments and your own reflections and subsequent responses (changes in approach, curriculum development, professional learning) in your teaching portfolio. Technique used to evaluate the curriculum There are many ways to evaluate the curriculum. Here are some common ways. Several of these would normally be used in combination: ? discussion with class ? informal conversation or observation ? individual student interviews ? evaluation forms ? observation in class/session of teacher/trainer by colleagues ? video-tape of own teaching (micro-teaching) ? organizational documents ? participant contract ? performance test ? questionnaire ? self-assessment ? written test

5.7 Challenges in curricular evaluation
Problems of Evaluation and Supervision (i) The greatest problem of education the world over is that of responsibility and control. According to Adeyinka (2008), "As a result of the prevalence of multiple system of education in the country, there is the problem of diversification and

165 control. Who controls what levels of education? Most times, people do not have the requisite skills to ensure that activities in schools are carried out in the most effective and efficient way possible. Some of which are the ability to find and interpret information and also communicate with people. Furthermore, people do shy away from evaluation because it exposes the weakness of the organization. (ii) Unstable subject syllabi: There are many examination bodies and there is need for schools and colleges to meet the requirement of the examining bodies. The school subject syllabi are changed or modified regularly. This poses a major problem to curriculum evaluation and supervision. Prospect for Curriculum

Development The numbers of pilot schools should be increase and fully utilized in order for the trial testing in curriculum development and evaluation.

For any new change in curriculum development, there should be regular annual long vacation courses for school teachers to get them acquainted to the philosophy, objectives, content and delivery method of project materials and also expose them to new techniques in education.

Mandatory continuing professional development. There is provision in the National Policy on Education relating to the continuous training of teachers and instructors. This will avail the teachers the opportunity to develop and demonstrate their profound competence against set standards. Use of information technology for teaching and learning: ICT programmes have been incorporated in all teachers training programmes. These will boast the curriculum implementation when fully harnessed. Furthermore, technology should be used in the curriculum development process to reduce the time taken to develop the curriculum. In using the electronic process, materials are developed and distributed on an information data base and made accessible to stakeholder to go through and make inputs. This reduces the meeting times and stakeholders. Grey areas are also involved using conference call.

166 5.8

Let us sum up In this unit we have discussed about the concept and need for curricular evaluation. We have also discussed about the important factors associated with curricular evaluation like learner, content, instructor and Resources. We came to know about different areas of curricular evaluation and different types of methods and tools for curricular evaluation. The unit ends with the discussion on the recent trend and Challenges in Curricular Evaluation. 5.9 Check your progress: 1. What is curricular evaluation? Explain the importance of curricular Evaluation. 2. Enumerate the important factors associated with curricular evaluation? 3. Explain in detail the Areas of Curricular Evaluation? 4. Which are the Methods and Tools for Curricular Evaluation? 5. Discuss the Challenges in Curricular Evaluation. 5.10

From the Vice-Chancellor's Desk Dear Students, from this Academic Session (2015-17) the Curriculum and Course Structure of B. Ed.- Special Education have been thoroughly revised as per the stipulations which featured in the Memorandum of Understanding (MoU) between the Rehabilitation Council of India (RCI) and the National Council for Teacher Education (NCTE). The newly designed course structure and syllabus is comprehensive and futuristic has, therefore, been contextualized and adopted by NSOU from the present academic session, following the directives of the aforesaid national statutory authorities. Consequent upon the introduction of new syllabus the revision of Self Instructional Material (SIM) becomes imperative. The new syllabus was circulated by RCI for introduction in the month of June, 2015 while the new session begins in the month of July. So the difficulties of preparing the SIMs within such a short time can easily be understood. However, the School of Education of NSOU took up the challenge and put the best minds together in preparing SIM without compromising the standard and quality of such an academic package. It required many rigorous steps before printing and circulation of the entire academic package to our dear learners. Every intervening step was meticulously and methodically followed for ensuring quality in such a time bound manner. The SIMs are prepared by eminent subject experts and edited by the senior members of the faculty specializing in the discipline concerned. Printing of the SIMs has been done with utmost care and attention. Students are the primary beneficiaries of these materials so developed. Therefore, you must go through the contents seriously and take your queries, if any, to the Counselors during Personal Contact Programs (PCPs) for clarifications. In comparison to F2F mode, the onus is on the learners in the ODL mode. So please change your mind accordingly and shrug off your old mindset of teacher dependence and spoon feeding habits immediately.

I would further urge you to go for other Open Educational Resources (OERs) - available on websites, for better understanding and gaining comprehensive mastery over the subject. From this year NSOU is also providing ICT enabled support services to the students enrolled under this University. So, in addition to the printed SIMs, the e-contents are also provided to the students to facilitate the usage and ensure more flexibility at the user end. The other ICT based support systems will be there for the benefit of the learners. So please make the most of it and do your best in the examinations. However, any suggestion or constructive criticism regarding the SIMs and its improvement is welcome. I must acknowledge the contribution of all the content writers, editors and background minds at the SoE, NSOU for their respective efforts, expertise and hard work in producing the SIMs within a very short time. Professor (Dr.) Subha Sankar Sarkar Vice-Chancellor, NSOU

10 1.1 Introduction You may be aware that curriculum includes all the necessary activities that are required to prepare the students to lead a successful life in the society.

The word curriculum is derived from the Latin root 'Currus' which means a chariot or runway.

It has the same meaning as word 'Curse' in English, it also closely resembles the term 'Karyakram' used in Sanskrit for any programme undertaken to be completed by individual or a group. Hence, curriculum is a programme of various activities of learning or studies taken up by a student over a period of time to achieve a goal in view.

This unit is intended to discuss the basic concept about curriculum development, its principles, procedures and changing trends in curriculum development of persons with mental retardation in inclusive set up. 1.2 Objective Explain meaning, definition, concept and principles of curriculum. Narrate types and approaches of curriculum designing. Demonstrate different curriculum domains. Explain steps, challenges of developing curriculum for inclusion. Discuss about curriculum evaluation and implementation in

inclusive set up. 1.3 Meaning, Definition, Concept and Principles of Curriculum Meaning : Neasly and Evans (1967) state that curriculum includes all the planned experiences provided by the school to assist the pupils in attaining the designated learning outcomes to the best of their abilities. The Key words here are 'planned experience' and 'designated learning outcome'. The provider is the special school or special educator in the context and receiver is the pupil the disabled child here. It is also essential as noted above that a good curriculum should assist in achieving the best of the students abilities. While keeping in mind the general curriculum principles, the special education curriculum should consider certain specific aspects.

11 Definition : Curriculum is the heart and soul of any educational process. It is the sum total of all that rendered by an educational institution in bringing out the required changes in the child. The activities range from class room to play ground or beyond. As you may have experienced, every society prepares the children in social competencies through the process of adjustment with the environment in which they live. The curriculum is an instrument to fulfill such objectives. Curriculum is defined by many experts. The common definitions are given below : Kerr notes that "

All the learning which is planned and guided by the teacher is carried out in group for individual inside or outside the school." According to Cunningham, "The curriculum

is a tool in the hand of an artist (teacher) to mould his materials (students) according to his ideas in his studio (

class room)." "Curriculum

includes the

totality of experiences that a pupil receives

through the manifold activities that go on in the school in the class room, library, laboratory, workshop, play ground and in numerous informal

context between

teacher and

pupil. In this case the whole of the school becomes the

curriculum which can touch the lives of the students at all points and help in the evolution of balanced personality" (

Secondary education commission 1952). "Curriculum can refer to

the total structure of ideas and activities developed by an educational institution to meet the needs of students to achieve desired

education al aims.’ (Dictionary of Education 1981). Concept : Simply put, curriculum is the content to be taught and instruction is the process of teaching. In other words curriculum is ‘what to teach’ and instruction is ‘how to teach’. Curriculum is not limited to the courses of study, but, includes what ever learning that takes place within and out side the class room and school; even planned social learning is include in the curriculum. Therefore, the curriculum can be content or subject matter taught to the students, pre planned programme, course offered in the school, intended learning out comes, cultural presentation and cultural reproduction, planned learning experience and social reconstruction.

Principles of Curriculum Development : The curriculum is a dynamic process of teaching-learning. In this modern age of science and technology, it is a programme which cannot remain static because, the 12 quantum of knowledge in all field is increasing rapidly and so is the quality of techniques and tools of instruction. The curriculum is ever charging.

It has to be planned, implemented, revised and reoriented from time to time. Hence, there are a few principle that are to be followed if the curriculum for any group of learners is to be conducted, and implemented. Goal-oriented Unless there are clear goals in view, the curriculum cannot be developed and implemented for any group. For example, if a programme is meant for a child without durability, the goal will be

to give him knowledge and competency on various subjects based on the norms. Therefore, the curriculum is subject-centered. If the programme is to be made for a child with mental retardation, the goal will be to develop specific behaviors or skills and therefore, the curriculum has to be skill-oriented and activity- centered. The goal determines the direction in which curriculum is to be shaped. Age appropriate The content of the curriculum should focus on the age of the learners. The contents selected for teaching in the kindergarten class will not appropriate for children of primary classes. It is because the ability, attitude and interest of a child

of higher age group will not match with lower age group. Similarly the curriculum set for a higher level cannot be used for children at a lower level.

Keeping in mind the Piagetian stages of cognitive development and the

developmental task pertaining to each stage, the curriculum must be planned according to the age and ability level of the child. Need based As every learner has defferent needs and abilities, the curriculum has to provide a variety of experiences in the class room

focusing on personal, social vocational and recreational needs. This principle is more relevant for children with mental retardation who have special needs as individuals. Each child with mental retardation is trained through planning an individualized Educational Programme (IEP) after considering their potentials and individual needs.

Children with mental retardation can benefit little from common curriculum with academic activities provided in group situation, as done for non-disabled children in regular schools. Though inclusive education measures are in progress, careful adaptation in content, process and evaluation are imperative for successful inclusion.

13

Level appropriate The pattern of the curriculum has to much the grade level of the learners. In a regular school, the content in any subject taught to children is based on the grade in which they are placed. For example, mathematics at primary level must be easier than that in secondary or higher secondary level. This

principle is most relevant for the children with mental retardation whose current level is to be determined before the IEP can

be devised. Up to date In this modern age, many changes and innovations are

taking place in the field of education and special education, based on the

research or experimentation. The curriculum should be revised and re-oriented periodically to incorporate the latest content, methods materials and techniques of the training and

Curriculum enrichment should be a continuous process.

Creative All children should get an opportunity to be creative and innovative. The curriculum must motivate children to solve problems, develop new ideas and meet challenges of life. Children should be encouraged to do experiment in classroom situation.

This is also relevant for children with mental retardation who also show creativity when they are properly motivated and guided.

The current trend of Activity Based Learning (ABL) provides ample opportunities for encouraging children to become creative.

Integrated At all levels, the Curriculum must be integrated and Cohesive and learning experiences are to be organized in a sequential order. Besides, it must relate to the activities of daily life (ADL) of children with special needs. This also means that the programme should be pragmatic and functional for learners. It should provide insights

for successful practical life leading towards habilitation and rehabilitation in case of Children with intellectual disability.

Comprehensive Curriculum

has to be

comprehensive enough to cover various co-curricular activities like arts, crafts, music, yoga, exercises, field trips, visits, concerts and cultural functions.

This principle is also applicable for children with intellectual disability who enjoy and participate in such activities more readily than in academic activities

involving

14

abstract concepts. Theme teaching is a good example of comprehensive approach which cuts across various academic areas through selected themes. 1.4

Types

and Approaches of Curriculum Designing 1.4.1. Types of Curriculum The

special educator will have to be aware of the following

five factors that act as guide in curriculum planning: 1. What is the main

goal or focus of curriculum? (Child, activity or situation as a whole?) 2. What are the

specific objectives that lead to achieve the goal? 3. What are the methods of instruction that are relevant in achieving the Goal? 4. What are the learning experiences/contents to be taught to achieve

the goal? 5. What are the materials needed to achieve the goal. Based on the above considerations, curriculum for special needs children have been evolved.

child centered curriculum. activity centered curriculum holistic curriculum. Child Centered Curriculum (CCC) In this, the child is in the centre of the Curriculum in

the teaching and learning process. The Child's ability, aptitude and interest are to be identified before a programme planned and executed. The child as an individual is valued and hence this kind of curriculum is child focused. This approach is very apt for children with mental retardation.

The main characteristic of the CCC are as follows: Basis CCC plan is based on the philosophy that each child is unique, each child is different and each child is an individual.

Each one should learn according to his ability aptitude and interest. The learner is the focus for whom the content and proceed decision will be made.

15 Aim The objective of CCC plan is to help each child to develop his skills, based on his abilities. It is to make him to realize

his best self and to achieve an optimum level of functioning.

Contents

Learning experience

should be provided according to the needs and abilities of

the child. Method The teacher will devise those technique of teaching and learning which will be suitable to the ability, aptitude and interest of each child. If

the child

is interested in play, the teacher will use the play way method of teaching and the objective will be entirely individualized and specific to the child. Materials The teacher will select/

develop the aids for learning suited to the age, ability and aptitude of each child. Pictures, charts, models and kits will be prepared with the special needs

of the child in view. Activity-Centered Curriculum (ACC) In

this plan, the activity or task is given more importance than the learner and his limitations.

Many a time it can be seen that the regular school curricula are activity centered as they are preplanned and the teacher is to focus on 'completing syllabus' rather than considering the pace of learning by the students. In the context of mental retardation

the important task or activities are identified for the benefit of the child and they are taught repeatedly through verbal, visual and real experiences in the class or out side. The child has to repeat the task or practice the skill frequently to

achieve maintain and generatize the learnt skill. The main characteristics of the ACC Plan are as follows: Basis ACC plan is based on the philosophy that task and skills are very important

and

the child must learn them through repeated programme in class and with frequent reinforcement by the teacher.

16 Aim The objective of ACC plan is to help the child

to develop certain skills so that he is able to improve his level of functioning. Contents The learning experience are related to task and skills which will be planned in advance. They are to be listed in sequential order and a detailed task

analysis is to be done for implementing the programme in class. Method The teacher has to use all available techniques to make the task easy and interesting. The techniques like task analysis, chanting, modeling, shaping and reinforcing and so on will used for teaching.

Materials The teacher has to prepare adequate teaching material in view of task or skill,

he is teaching the child. He has to

use a blackboard, charts, pictures, models, flash cards, audio visual aids, and

field trips to make the task a meaningful learning experience. Holistic Curriculum (

HC) A holistic curriculum is an eclectic model blending the needs of the child and the existing curriculum the right combination of what is expected from the child.

The main characteristic of HC plan are as follows: Basis HC plan is based on the philosophy that the life of a child is integrated with his total environment. He should trained in a

manners to master a few skills, so that he can become independent as far as possible.

Aim The objective of HC plan is to help the child

to

achieve competence and confidence in life as an effective and productive member of the community. Contents The learning experience as widely selected to expose the child to his full development and total adjustments within his social,

economical, and vocational environment in 17 life so that when he grows as an adult he will be a contributing member of the society. Therefore, emphasis will be on different kinds of functional activities, skills and experiences that make the child a successful person. Method The teacher has to use a variety of methods of teaching. Class room techniques alone will not be adequate. So the teacher has to organize visit, field trips, demonstrations, projects, exhibitions to give the children sufficient exposure to the world outside. It will help them to gain confidence and become competent in life.

Materials

The teacher will have to use a wide variety of teaching materials in the classroom as well as out side the classroom. The materials can be pictures, charts, models, objects, tools, audio-visuals, films, filmstrips, flash cards and even visits and field trips outside the

class-room. 1.4.2. Approaches to Curriculum Designing

There are varied approaches to development of curriculum. Some are common in both general and special education while some are more suitable for

children with special needs. It is the responsibility of the teacher to select a suitable approach or a combination of more than one approach with the aim to reach the student with the most suited curriculum and instructional process.

Some of the commonly used approaches include. Developmental approach Functional approach Ecological approach Unit approach Development approach Developmental approach pertains to integration of academic learning and developmental tasks aiming at accomplishing the ultimate goal of individual potentials, and the global needs and motives. The curriculum includes, instructions for achieving maximum possible personal enhancement and social competence.

18

Development approach of

the curriculum focuses on the learner's growth (Physical and mental) activities, aptitudes and interests. The programme should be related closely to each child as an individual, his development in term of capacities and limitations, keeping in mind, the developmental norms and the tasks that he is expected to perform in that age.

The aim is to help the individual to grow up and to lead a productive adult life. The teacher has to diagnose the special needs, deficit skills and unique talents of each child and then develop a programme as a personal package with all the necessary content, materials and techniques of training and management.

Functional approach

Ideally in special education as in regular education, the curriculum should be derived from an analysis of the needs of the individual and the role he is expected to perform in the society. Therefore, a good curriculum should be focus on imparting social competencies to children with intellectual disability so

the

they live as independently as possible in the community. With the trend toward inclusive education, the curriculum for children with mental retardation is generally an adaptation of the regular education curriculum with a focus on vocational education. This training allows for appropriate job placement of the child when he is ready for it. Such a curriculum includes

functional reading, writing, arithmetics, time, travel, money and other related skills.

Generalization or

transfer of classroom learning to application of skills in natural environment is an important aspect of this curriculum.

Curriculum

used with children who are moderately and severely retarded emphasize training as on functional activities.

The content of the curriculum are chosen from various tasks that have a high probability of beings required in day-to-day living. These tasks include personal, social, occupational and recreational activities. Academic skills are incorporated where the children have ability to learn.

Considering the unique needs of the child, the content, process and materials are planned to achieve independent functioning level.

A functional approach to the curriculum designing

means the programmes should be planned and implemented with view to improve functional competencies of children in activities of daily living (ADL)

such as brushing, dressing, eating, drinking, toileting, communicating and so on.

These activities make the child competent in performing day-to-day tasks and attain an independent level of functioning.

Functional academics

is incorporated when the children have required ability.

Ecological approach Wallace and Larsen (1978) have pointed that if a child is to be assessed, it is essential

19 that various environmental factors should be taken into consideration to determine their influence in either imitating or maintaining a skill or behavior.

For instance, a child with mild mental retardation in an urban environment becomes a cause of concern to parents as early as at pre-school (LKG / UKG) level, when the parents find him to be subnormal in school. On the other hand, "in a rural area even with mild mental retardation might be

well

accepted without any problem. He might be performing the major work output expected of him in the rural area, which may be

agriculture, dairy or poultry farming which his fellow men do.

An ecological orientation to a curriculum means the programmes should be planned and implemented, keeping in view the environmental factors that influence a child's life. Ecology includes all the factors affecting a child such as natural geographical, urban, rural, social, cultural and vocational factors. The curriculum has to help each child to be productive and effective members of community when grows up. It is more relevant if it include all the environmental factors or situations in which

the

child lives at present. In other words, the curriculum should incorporate instructions in those situations which are closely related to his natural environments viz, personal, social, school, recreational and vocational settings

while planning the curriculum the teacher assesses the student's present and future environment and then, compares the environmental details to the child's abilities. This generate a picture of discrepancy between the environmental demand on him and the child's current abilities. Then the teacher will follow accordingly curriculum to fill the gap.

Unit approach/ thematic approach

It is based on teaching concepts through themes. For example, if transport is taken as a theme, reading, writing, math, environmental science—all will be taught through the theme of transport. The content will be level appropriate. A pre-primary curriculum may talk of modes of transport while a prevocational curriculum may include the professions related to transport systems and various skills needed to learn while traveling in each of the modes, such as money, time, measurement skills (distance) and so on. As this approach is activity oriented and based on the concrete experience, this is suitable for children with mental retardation at all levels and can be taught in group situations also. It should be kept in mind that it needs prior preparation, resources, systematic planning, implementation and evaluation systems.

20 1.5

Curriculum Domains—Personal, Social, Academics, Recreational and Community Living. The currirulum content for the children with mental reterdation requires focus on

leading the students towards personal adequency, social competency and economic independence.

The curriculum

for the children with mental retardation

includes coree

areas such as personal, social, functional academics, occupational and recreational skills with the aim to prepare them for independent living.

If we aim to prepare persons with

mental retardation to lead life with independence and dignity and to become a contributing member of the society is warranted, then the above mentioned content areas should be considered.

1.5.1. Personal Skills

Personal skills include eating toileting bathing, brushing and grooming. The tasks involved in these skills vary for children of different ages and level of functioning. For example dressing skills at preprimary level may refer to wearing clothes but the same dressing skill at secondary level may mean selection of the right clothes to wear for an occasion matching accessories for the dress. Ironing of clothes and maintaining their wardrobe and so on. In addition, to perform the tasks in any area, appropriate motor skills (gross motor and fine motor), language and communication skills are also required. For example pouring water from the water filter and drinking from the glass. The girl has to go to the kitchen, identify the glass and take the glass, open the tap (finger grasp), pour water in the glass, close the tap and drink from the glass. Another example can be considered, the family has gone to visit their friend's house and the girl feels thirsty. They has to communicate to her mother or the host (Communication) that she needs water. Therefore, we need to remember that skills are not taught in isolation but they has to be generalized. Personal domain include the following skills which are to be taught to the children with intellectual disability: Eating and Meal Time Management Toileting Bathing Brushing Grooming skills

21 Dressing skills Menstrual hygiene Shaving

1.5.2. Social Skills

Social behaviour of the students play a vital role in their independent living. Many of the children with mental retardation behave inappropriately in the social situations. Therefore, teaching of appropriate social skills is a major focus in the curriculum for children with mental retardation. These skills are related to social exchange coping with demands of environment and controlling impulses. It also includes the development of social skills to respond to situational cues and making choices. To be accepted as a member of the group and part of the community, one needs to have good interpersonal relationship. The main areas where social skills need to be taught to the children are as follows: Situations in school, in neighbourhood and in the community Standing in a queue, sharing, turn taking behaviour etc. Travelling by buses, trains and crossing the road with safety. When bullied, beaten or in distress, asking for help/ managing the situation is also a social competency to be taught. Acceptable and appropriate interpersonal behaviour in home, school, community and any other social situations. Taking care of personal belonging, understanding of right and civic roles etc. Language and Communication Skills Languages and communications are means of socialization. Like social skills language and communication help us to interact with the environment and therefore, communication must become part of all activities. While teaching young children the following points should be considered :- Proceed from known to unknown. Use various co-curricular activities for training. Use all modes of Communications.

22 Include scope for field trips Use playway methods.

To teach social and language skills the school should focus on: Greeting people and use of polite gestures and courtesies. Group game Story telling Narrating experiences. Discussing important news (TV / News papers / neighbour hood) Receiving and passing on telephonic message to appropriate person. Getting involved in various functions in the school. Maintaining conversations. Activities at home can include social training like Greeting people and courtesies. Interacting with family members and guests. Attending social and religious functions. Sharing experiences with siblings. Receiving telephone calls. Going out with family. In addition to developing appropriate social behaviours, we have to reduce the socially inappropriate behaviours.

1.5.3.

Academics. The functional academic refer to the literacy and numeracy skills. The children with mental retardation need to learn these skills

for leading independent lives. It includes reading, writing and arithmetics.

Functional Reading Functional reading is defined as student's actions or responses resulting from reading the printed word.

Primary goal is the development of their ability to read signboards,

23 labels, directions and so on (

concept of survival)

for their protection.

The second goal is reading for information and instruction -newspaper, telephone book, job application and so on. The

third goal is reading for pleasures-magazines, comics, story books

etc.

Whole word approach is a widely used method in teaching functional reading. Through the whole word approach the students learn to recognize and read words and later receive decoding instructions (to spell).

A variety of strategies have been used in teaching sight word vocabulary. Recent attention has been focused on the imagery level of the word to be learnt.

High imagery words are usually concrete and include nouns such as ball, mango fan and house. Low imagery include abstract terms such as beautiful, good and have. In some instances high imagery can be provided for low imagery words by using the word in context. For example, consider the word 'Sour' "I ate mango. It is sour", becomes more concrete and student can remember better. Pairing of words with concrete objects and /or pictures will facilitate development of high imagery level in the students. Here, the concrete word 'mango' helps in learning the abstract word 'sour'.

Functional Writing One of the important modes of communication is written expression. Writing demands eye hand co-ordination, motor co-ordination,

sense of direction and recognition of symbols (Pictures/ Letters/ numbers/ Words/ Punctuations and so on). Some writing tasks demand horizontal writing (

left to write as in writing words)

and some demand vertical writing as in arithmetics (addition, subtraction) and some demand a combination of both as in statement sums. Tracing writing involves four stages.

They are: 1. Tracing 2. Joining dots (

if needed) 3. Copying 4.

Fill in the blanks 5. Writing from memory (including spelling learning) To write sight words, students have to go through steps using auditory, visual, tactile and kinesthetic inputs.

24

Functional Arithmetic We are in daily contact situations which require the use of number skills.

For example, when we buy half a dozen bananas from the fruit vendor we glance at the bunch to check whether it contains six bananas or not. We use number skills in various setting such as at home, in community and at work place—how many plates to place on the table, which bus number to take to reach work place how much is the bus fare, how long it takes to reach office and so on.

Before beginning with numbers, make sure the child is aware of pre-math concepts

or is able to generalize the pre-requisite skills to mathematics

such as more less, far- near, heavy-light, tall-short-long,

left-right,

one-money,

and so on. The following are the points to be considered while planning and teaching arithmetic skills: The content should be arranged us a sequential order for which the task analytic approach is applied.

Use concrete materials

for meaning of concepts. Meaningful materials should be widely used inside or outside the school. Teach concrete to sub concrete then to abstract. Instruction must be practical and functional. Oppertunities of sufficient practice. Provision of generalization beyond the classroom.

Programme must be flexible to meet the individual child's need. A functional mathematics curriculum should include use of calenders

time, money, measurements (mass, volume, weight, distance) which are necessary for daily living activities. The content must be graded from easy to difficult, distributed from pre primary to prevocational levels. 1.5.4.

Occupational Skills Occupational skills are essential for the overall development of persons with mental retardation. To prepare an individual with mental retardation for independent living, training in over all developmental skills is important. Occupational skills includes activities such as cooking, shopping, gardening and house keeping. However, the curriculum content

for pre-primary and primary level will be less when compared in

25 secondary and prevocational level. As the child is promoted to the next level the occupational skills increase proportionately in the curriculum content and the personal skills will reduce as he would have gained competency in most of the personal skills. Introduce the skills in school and teach the children. Simultaneously, keep the family, informed and involved so that they extend the training at home too. Such activities can be household activities, such as sweeping, dusting, washing, peeling, cutting vegetables and so on.

Identifying and reading label on edible items, writing a shopping list are also other examples.

Performing these activities require application of functional reading writing and arithmetic skills.

Through the joint efforts of school and

home, appropriate work habits, punctuality, regularity, sincerity, persistence, proper work behavior, hand functioning, eye hand coordination and required community living skills (travelling, shopping, banking skills) can be taught to the students. Eye hand co-ordination

and hand functioning which are important prerequisite skills for any vocation can be improved by activities such as: Cutting, pasting Sorting, peeling, shelling, cutting vegetables. Using of different hand tools, files.

Screwing and unscrewing. Sewing, knitting. Pouring and keeping water bottles. Dish washing and arranging. In the school, engage the students in various simulated activities to assess the interests of the students.: Wood polishing, cutting, nailing, screwing. Assembling Labeling different items/tools (in the workshop) Binding and painting work.

Sewing and knitting. Packaging work. Gardening (Cleaning gardens, watering plants and planting)

26 Operation of different machines. Various community living skills by organizing following activities for students

Preparation of shopping list Budgeting Shopping Banking, post office, hospitals—attend and use. Use of public transport.

Domestic Skills Dusting, sweeping, mopping. Washing utensils. Cooking simple meals or helping in cooking. Washing clothes, drying, folding and ironing. Packing lunch boxes. Buying vegetables. Stitching buttons on garments. Decorating house during festivals. Booking LPG Cylinders. Paying bills. In short any useful activity that is repetitive and frequently used but does not require decision making abilities can be taught to persons with mental retardation. School curriculum has to play an important role in developing these skills with the children as these are absolutely functional and of high value to the child and family in making him a contributing member to the home and society. This is what the purpose of functional curriculum is.

27 1.5.5. Recreational Skills Play is

a major component in the curriculum. Research evidence shows that children with limited play skills and

who were rarely touched had brains that were 20-30 percent smaller than normal (Nash 1997, as quoted by

Chen 1999). Young Children who have severe and multiple disabilities need training to use their senses and physical abilities to

carry out activities. Such training will help the child to understand information by exploring the environment. By exploring in environment helps to develop

concept mobility and communication. Persons with disabilities also requires time for recreation. Many a time, they are unable to decide the activities for

the recreation. In the school time table there should be

the time slots for recreational activities when students can be given opportunity to participate in various co-curricular activities. Use of leisure time and engaging in recreational activities do not come naturally to persons with mental retardation. They need to be prompted to take part in such activities.

After finding out their aptitude and interest they should be involved

in suitable activities. Recreational activities should take a significant place in the overall

curriculum. 1.6

Steps in developing curriculum, challenges of developing curriculum for inclusion. 1.6.1. Steps in developing curriculum
The curriculum development process can be divided into six steps. They are: Formulation of objectives. Selection of learning experiences Determination of the content. Preparation of learning materials/activities. Implementation Evaluation. These steps can be arranged in a sequential order

28 Formulation of objectives. ? Selection of learning experiences ? Determination of the content. ? Preparation of learning materials/activities. ? Implementation ? Evaluation. Assessment of Educational Needs India is multi-cultural society. Since the background of students different from culture to culture, place to place, time to time, even student to student in a class room, it is important to assess the individual need of the students. We should identify the needs of the target group for whom curriculum is to be developed. As a first step, the curriculum planners should make a need analysis of different categories of learners. This analysis leads to a detailed description of activities, the requirements and expected learning experiences. It provides details of the knowledge, skills and attitudes required by/individuals to perform the tasks involved in learning a concept. Formulation of objectives Objectives should be grouped in terms of three domains—cognitive, affective and psychomotor. Proper grouping of objectives will help us in planning and developing a meaningful curriculum in terms of the suitability and relevance of its content and evolution. For each need of the learner, there should be corresponding objectives. Hence, these can be as many educational objectives as the educational need are. Each educational objective will suggest a series (and a variety) of learning experiences. Objectives will be most functional if they are stated in terms of expected behavioural changes in the students of the going through teaching/instruction/schooling. Attainment of objectives should lead the learners to attain overall goal(s) of education. 29 Objectives should be modified updated or eliminated based on the changing needs of the students and the society this would help to maintain the quality of education. The statement of objectives should be worded properly so that the learner and the teacher are able to understand the intended outcomes. Selection of learning experiences Early experiences include physical, mental and educational experiences and their interactions. These bring desirable changes in behaviour of the learners. And change in the learners will lead to the attainment of curricular objective. Criteria of selection of learning experiences are as follows: A learning experience should satisfy the recognized needs of the learner. It should be appropriate to the maturity and understanding of the learner. It should build towards consistent continuing and dynamic goals. It should be based on social values. It preferably should be positive. It should be realistic. It should be efficient. It should not be limited by artificial barriers such as the four walls of the class room. Learning experiences should involve total behaviour. It should be feasible for accomplishment. Determination of the Content. Contents refer to the subject matter or the compendium of facts, concepts, generalizations, principles and theories. The subject matter to a large extent, contributes to the growth and development of a democratic, secular and socialist society. So, the content is considered as one of the most important components of curriculum development. The following can be considered while selecting the content: Is the subject matter significant to an organized field of knowledge? Is it useful? Is it interesting enough to the learner? Does the subject matter contribute to the growth and development of a democratic society? Apart from the above, content should have the following characteristics: The content should help the learner to become self-reliant and self-sufficient. It should be significant in contributing to basic ideas and concepts.

30 The selected content should be valid so that it should fulfill the objectives and goals of education. It should suit the personality and intellectual capabilities of the students. It should be useful in the job situation of the learners. It should be feasible in terms of time, costs and contemporary social climate. Preparation of learning materials/activities By now you have studied about assessment of educational needs of the learners, statement of objectives, and identification of the contents. This is done by preparing learning materials/activities. Learning experiences and contents of organizing, integrating and sequencing of materials and activities depend on the availability of learning situations in the schools and classrooms, infrastructural availability, developmental levels of learners, principles of learning and the cultural contexts of students and teachers. Learning materials include anything that leads to learning such as, text books, supplementary readers, audio and visual programme and other relevant teacher made material. Preparation of learning materials is a complex task, it demands a through understanding of the teaching-learning process. As you have already learned, Bruner talks about three modes of learning. They are. Enactive mode – activity based learning. Iconic mode – learning by use images diagrams. Symbolic mode – Learning by use of symbols/languages. There are various criteria for selection of learning materials depending on the selected mode of learning. Wood (1963) has suggested six criteria for learning materials. They are as follows: All learning materials should make a definite contribution to the satisfaction of recognized need on the part of the learner. They should be a variety of learning materials to provide for the individual differences, usually found in a group of students. Learning materials should be as authentic as possible. This will tend to increase the objectivity of analysis and the accuracy of conclusions drawn. Learning materials should be selected on the basis of efficiency. These materials

31 that result in the greatest amount of learning in the least amount of time should be given preference. Economy is always a factor if there is a choice between two types of materials of equal learning value, the less expensive one should be chosen. Even neither when the learning values are not quite equal, practical factors may demand the choice for the less expensive one.

Implementation After the preparation of learning materials/objectives, the next step is the implementation of the curriculum in the classroom. This is the stage of actual teaching learning or transaction of curriculum. Teachers, Principals, Supervisors and Members of school management are involved in the proper implementation of the curriculum. Agarwal (1990) suggested the following major factors leading to the efficient implementation of the curriculum. Adequate preparation of the teachers by the Boards and State Department of Education for meeting, the changed requirements of the new curriculum Sufficient supply of the teaching aids and equipment is needed for the impelmentation of the curriculum. Community participation with curriculum. Adequate preparedness of the students to accept the curriculum with its additional requirements of energy, money and time. Adequate supervisory and guidance facilities for teachers needed for effective implementation on the curriculum.

Evaluation An essential aspect of good curriculum is the evaluation of curriculum, which should be continuous. The primary purpose of evaluation of curriculum is to ensure quality control and suitable modification in the curriculum. Evaluation may be qualitative. It may be done both at 'macro' level as well as micro level. It also may be done both at formative and summative stages. Curriculum evaluation determines the worth of curriculum. It determines, whether curriculum fulfils its purpose for which it is planned. 1.6.2 Challenges of Developing Curriculum

for inclusion Historically, educational services for children with mental retardation where designed to be provided in segregated settings. With the efficacy of research done in recent 32 years, the idea of providing services as close to the normal environment as possible has become the trend to inclusion. When developing such a programme, the varied needs of children with mental retardation with various culture practices should be taken into consideration. This makes it defficult to develop an ideal curriculum and plan programme uniformly. This is also one of the reasons for not having a common curriculum for all the individuals with intellectual disability.

As suggested by Lieberman (1992) the curriculum for children with mental retardation should therefore focus on: 1. The need of the students. 2. the probability that the intervention requires a special set of arrangements that are generally not available in regular class room settings. It is imperative that the shift of emphasis is made in curriculum priority from academics in regular classrooms to student based needs. When curriculum has to focus on all-round development as mentioned earlier, it should

be need based. It has to take into account the functions to be performed by the individual in his environment and the required competencies for it. Baine (1991) recommends an ecology based curriculum where the task involves assessment of not only the person with intellectual disability but also the functions he has to perform along with non disabled persons in a given environment. This allows for a discrepancy analysis, leading to specific focus on the strength of the individual with intellectual disability and selection of appropriate tasks and activities to be taught as suited to his environment.

The

approach being a functional one is likely to be meaningful to the individual if used at secondary school level. The primary level curriculum for children with intellectual disability will predominantly include personal, social, basic academic and introductory occupational skills. Co-curricular

activities, recreational and leisure activities should not be ignored and should be included as in the regular school curriculum. Infactt inclusion will be

more meaningful in the schools when recreational and leisure activities are planned for children with mental retardation along with those for non-disabled school children. When functional academic area is planned in the curriculum, it should focus on those areas which will

be of utility to the children with mental retardation. It is a waste of time teaching those activities that they will not use in present or future environments,

33 because, it is the need/opportunity for application of what is taught and what will benefit them. A study (Narayan and Myreddi 1996) was conducted to compare the functional curriculum with the one that is in use at regular schools. Minimum level of learning (MLL 1992) as prescribed by NCERT was item endorsed with the listed thing in the Functional Assessment Checklist for Programming (FACP) (Narayan et as, 1992) from preparimary to prevocational level covering the ages of 3 to 18 years for children with mental retardation upto prevocational age level happens to cover about 43% of the regular curriculum upto class III. The coverage showed 65% of class I. 42% of class II and 23% of class III. This again emphasized that primary education covers functional skills to a large extent making it possible for children with intellectual disability to learn. The essence of need based content area from regular primary education can be included in the curriculum area for academic learning of children with mental retardation. As they grow older or move to higher classes, need based education with ecological consideration is more suitable with specific evaluation criteria.

The cultural trend towards inclusive education, poses yet another challenge, the educators will have to face. The concept of inclusion demands that all children should be part of the educational and community mainstream. The Persons with Disability Act India (1995) also highlights equal opportunities for all support of inclusive education

and special education and the new role to which they have to adapt themselves. The peer group adjustment, the resource requirement and administrative decisions are other components of this concept. In India, the inclusive education is at infancy demanding tremendous efforts by all concerned to study its efficacy. In Short The curriculum should be developed after identifying the functional daily activities that are to be performed by the child with mental retardation in a given environment, may it be urban, rural, industrial, slum or semi urban areas. The curriculum should include specific activities that need to be mastered rather than are broad skill areas such as gross motor, fine motor, and socialization, language and so on. The Curriculum should emphasise process of training to be conducted as far as possible in the natural environment and that steps should be taken to minimize transfer of learning.

34 The inclusion of academic skills in the curriculum such as reading, writing and arithmetic must be absolutely function oriented and that the person with intellectual disability uses the skills learnt in his daily living. For instance, some times, the

special educators have their students working on 2 digits, 2 line additions on paper, but unable to say correctly, if they asked, orally, three cars and four autos make a total of how many vehicles. This happens because the addition taught on paper has not function oriented and was not generalized. Therefore, the curriculum must relate academic to its function in day to day life. In addition to academic skills, self care and communication skills, the curriculum should provide for recreational skills, home management skills, health and safety and community oriented skills which contribute to social competence. Though the initial instructions of certain skills begin in classrooms, as the child learns the skills and gains mastery over them, they have to be community referenced, as eventually a person with mental retardation has to live in the community. The curriculum should take into consideration, the economic, social, cultural and such environmental characteristics of the society in which the person with intellectual disability live. This should be emphasized especially in the aspects of vocational training. Local resources and occupations must be taken into consideration and the person will be trained accordingly. To conclude, a good curriculum should take into consideration the environments in which the persons with intellectual disability lives namely, home and family, community, school, vocational and occupational areas. The skills should be identified, organized, sequential and the training should be given in the natural environment. By this, the person with intellectual disability is taught what is required for him to be independent in his society. 1.7

Curriculum evaluation, Implementation in inclusion 1.7.1. Curriculum evaluation Curriculum evaluation refers to evaluation of the defferent components of Curriculum, namely objective, contents, learning materials, teaching strategies and students evaluation procedure.

35 The purpose of Curriculum evaluation is to get feedback for further modification and refinement in the curriculum. Curriculum is a complete design of planning. All teaching learning procedures are directed by this planning. So quality of curriculum is equivalent to the quality of education. Therefore, curriculum evaluation is the essential part of the education valuation, draws on one's judgement to determine the over all value of the Curriculums Evaluation of Curriculums Contineous. There are mainly two types of curriculum evaluation namely summative and formative evaluation. Summative evaluation: Summative evaluation takes place after the implementation of the curriculum and learning and provides information and feedback that sums up the effectiveness of curriculum. According to A. J. Nitko (1983), "Summative evaluation describes judgements about the merit of an already completed programme, procedure or product." Objective of summative evaluations: Whether the Curriculum is appropriate for the particular level/class. It helps to determine the ultimate out comes of the students and their curriculum. Whether it is designed as per the needs of the students with intellectual disability. It helps to connect between the ultimate aims and immediate aims of the curriculum. It determines the time limit of the curriculum implementation. It helps to link between present level and subsequent level of the curriculum designed for the children with intellectual disability Characteristics of the Summative evaluation: It leads to the use of well-defined evaluation designs. It focuses on analysis. It is concerned with broad range of issues. Its instruments are reliable and valid. It tends to stress local effects.

36 Advantages of Summative evaluation of Curriculum: It is time and cost effective. It is least complex in nature. It can be done by the teachers. It is more reliable and valid. It helps to determine the incompleteness, errors and problems of curriculum. Disadvantages of Summative exaluation & Curriculum: It is very difficult to evaluate the curriculum during the implementation. Under qualified teachers can not evaluate properly. It involves the intellegence, interest, motivation of students which are very difficult to relate with the curriculum. Evaluation may be affected by the use of unappropriate tests. Formative evaluation of Curriculum Formative evaluation of curriculum provides feedback and information during the implementation process, while learning is taking place and while learning is occurring. Formative assessment measures the curricular aims, objectives, teaching strategies. curricular contents, teaching-learning materials selection, instructional methodology, students progress including learning out comes and teachers competencies in the present Curriculum. A primary focus of formative evaluation of curriculum is to identify areas like objectives, contents, teaching strategies, methodology etc. that may need improvement. Formative evaluation is to determine teaching effectiveness and curriculum relevancy. Formative evaluation has allowed to 'rethink' and 're-deliver' that objectives, contents, selection of materials teaching strategies etc to ensure the curriculum is on track. Characteristion of Formative evaluation: It relatively focuses on molecular analysis It is cause seeking. Its design is exploratory and flexible. It tends to ignore the local effects of a perticular programme. It seeks to identify influential variables.

37 Stage of formative evaluation of Curriculum Stage 1. The aim of this stage of evaluation is to evaluate the basis of the curriculum. It is very important to assess the physical and mental status of the learners which is comparable to the basis of Curriculum. Stage 2. Accumulated basis derived from the Stage 1 should be verified properly. The aims of the curriculum should be evaluated in this stage. Stage 3. In this stage the curricular contents need to be verified. Stage 4. Evaluation of implementation including methods, teaching strategies is also an important part. Stage 5. Evaluation of the arrangements of Curriculum contents is the main task of this stage. The infrastructure, competencies of teachers, socio-economical needs etc are also to be evaluated during the formative evaluation of curriculum. Advantages of formative evaluation: It helps to keep the curriculum almost errorless. Every stage of curriculum are verified appropriately. It helps to predict the effectiveness of curriculum in advance. Preparation of teachers training can be done in well advance. Disadvantage of formative evaluation: It takes long time. It requires involvement of experts, people and various organizations. Effectiveness of the curriculum may decrease as formative evaluation takes a long time. 1.7.2. Implementation in inclusion The academic learning and the abstractions involved in it makes it difficult for a child with mental retardation to cope with regular curriculum in inclusive set-up. Janney & Snell (2000) offer three considerations in curricular adaptation (1) Simplified, (2) Supplementary and (3) Alternative which are very essential for implementation of curriculum in inclusive education.

38

Simplified curriculum Simplified curriculum includes fewer concepts and skills rather than the entire scope of the general curriculum. Example: Structure and functions of part of the eye. The text books have detailed description of parts of the eye. Iris, pupil, cornea, lens, aqueous humor, vitreous humor, optic nerve with difficult terminology and the functions eye. A child with mental retardation can just be taught major parts and functions. The parts that are visible so he comprehends (eyelid, pupil, iris) and focus on care of eyes, symptoms of problem of eyes, care of the eye glasses and such other information which is more functional and simplified and taken from regular educational curriculum.

Supplementary Curriculum Supplementary curriculum includes basic skills such as reading, writing, maths and also social skills, study skills and learning strategies. This helps children in organizing themselves to improve memory and helps in learning. This type of curriculum is most useful for children with learning disabilities and these who have emotional/behaviour problems. Example: Student attends regular class but performs poorly in exams. In such cases supplementary classes are provided

for test taking, organizing time, paraphrasing, noting main points and practicing test taking skills.

Alternative Curriculum An alternative curriculum emphasizes skills needed to participate in activities in the community living. An alternative curriculum therefore, can be functional, community referenced curriculum, determined by assessing the student and his environment. Functional academics forms part of the community referenced curriculum. Depending on the level of retardation, emphasis can be given on personal, social and

communication skills. Opportunity for partial participation in school activities is recommended for children with severe retardation. Example: If in the class curriculum demands 'gardening activity' a severely disabled child may perhaps participate by holding the hosepipe with the help of his/her peer for watering plant. He may receive his individualized instruction which may have minimum common content with his age appropriate regular curriculum. It is an alternative curriculum with the common objective of leading towards independent living.

39 In inclusive set-up the:

peer-tutoring, team-teaching unique teaching strategies uses of effective teaching learning material reduction of subjects extension of the time to complete curriculum flexibility of examination system can be beneficial for the children with intellectual

disability. 1.8 Let Us Sum Up We discussed in this unit underlying meaning, definition, concepts and principles of curriculum which are goal oriented, age appropriate, need based, Level appropriate, upto date, creative, integrative and comprehensive. We discussed the different types and approaches of curriculum, designing which includes child centered curriculum (c.c.c), activity centered curriculum (ACC) and holistic curriculum (HC) types and different approaches like– develop mental approach, functional approach, ecological approach and unit approach. The curricular contents for children with intellectual disability focus on personal, social, academic and occupational domains. All these areas covered in curriculum content at all levels. A combination of various techniques has to be used while teaching a particular skill and can use different techniques for different students even for teaching the same skill. The curriculum, stages moves sequentially from formation of objectives to the evaluation. We discussed the curriculum evaluation which includes summative and formative evaluations of curriculum. Lastly we discussed the implementation of curriculum in inclusion using different curriculum adaptations like simplified, supplementary and alternative curriculum. 1.9 Check Your Progress 1. Define curriculum. Is curriculum same as syllabus? Discuss.

40 2. Describe any 2 principles with examples to be taken into consideration while constructive the curriculum in the context of intellectual disability. 3. Compare the developmental, functional and approaches to curriculum development and highlight the similarities and differences. 4. Think of a theme and group of children in preprimary to prevocational levels. Narrate how the theme chosen by you will provide the cencipts suitable at each of these level. 5. Development of personal skills varies according to culture and region. Discuss. 6. List social skills that you will include in primary level curriculum. 7. Discuss the methods of teaching functional academics to children with ID. 8. Prepare a list of resources available in our community to teach occupational skills for students with intellectual disability. 9. Write the various steps of curriculum development in sequence. Explains with example. 10. Assessment of educational needs is an essential component of curriculum development. Discuss. 11. Write different advantages and disadvantages of summative and formative evaluations of curriculum. 12. How do you implement the curriculum in inclusion? 1.10 References :

Let us Sum Up 2.9 Check your Progress 2.10 References 2.1 Introduction

Early childhood is

a crucial stage of life in terms of a child's physical, intellectual, emotional and social development. Growth of mental and physical abilities progress at an astounding rate and a very high proportion of learning takes place from birth to age six. It is a time when children particularly need high quality personal care and learning experiences. Education begins from the moment the child is brought home from the hospital and continues on when the child starts to attend playgroups and kindergartens. The learning capabilities of humans continue for the rest of their lives but not at the same intensity that is demonstrated in the preschool years. With this in mind, babies and toddlers need positive early learning experiences to help their intellectual, social and emotional development and this lays the foundation for later school success. Children taught at an early age usually benefit in the following ways: improved social skills, less or no need for special education instruction during subsequent school years, better grades, and enhanced attention spans. Likewise, some researchers have concluded that young children enrolled in pre-school programs usually have fewer behavioral problems, and do not become involved with crime in their adolescent and young adult years. The three broad objectives of ECCE are: holistic development of the child to enable him/her to realise his/her maximum potential; preparation for schooling; providing support services for women and girls.

44 The curriculum is defined as age appropriate, all round, play based, integrated, experiential, flexible, and contextual. The guiding principles of the ECCE curriculum are: Play as the basis of learning, Art as the basis of education, Recognition of the special features of children's thinking, Primacy of experience rather than expertise Experience of familiarity and challenge in everyday routines Mix of formal and informal interaction Blend of the textual (basic literacy and numeracy) and the cultural elements Use of local materials, arts, and knowledge Developmentally appropriate practice, flexibility, and plurality Health, well-being, and healthy habits Globally, many events have contributed to the realisation of the significance of the early childhood years for a country's economic progress. The beginnings of this change started with the United Nations Convention on the Rights of the Child in 1989. For the first time, there was a set of international standards and measures intended to protect and promote the well-being of children in society. The second major event that drew attention to the issue of early childhood was the creation of the Human Development Index, a summary measure of human development, by the United Nations Development Programme (UNDP) in 1990. The Human Development Index measures the achievements of countries on three basic dimensions of human development: (1) a long and healthy life; (2) knowledge; and (3) a decent standard of living; it includes indicators that specifically relate to children, namely, mortality, education, and child labour. The third important event in the international arena was the World Conference on Education For All (EF A), held in Jomtien, Thailand in 1990, where a global commitment to education was made in a document beginning with the famous words 'Learning begins at birth'. In addition, the World Education Forum, held in Dakar, Senegal in April 2000, reiterated the importance of ECCE through the involvement of the state, the family, and the community. India is signatory to all these agreements. 2.2

Objectives After going through this unit you will be able to

Discuss the different

curricular domains in preschool education. Discuss the significance of preschool education. Narrate the role of parents in preschool and primary education. Discuss

the importance of record maintenance. 2.3 Significance of Early Childhood Education And School Readiness

All children need and deserve a good start. Attending high quality early childhood programs is an important part of starting early and starting right. 2.3.1 Early Childhood Education and School Readiness: Early childhood is defined as the period from conception through eight years of age. The earliest years of a child's life are critical. These years determine child's survival and thriving in life, and lay the foundations for her/ his learning and holistic development. It is during the early years that children develop the cognitive, physical, social and emotional skills that they need to succeed in life. These early experiences are largely determined by supportive family and community care practices, proper nutrition and health care, learning opportunities, which in turn are dependent on enabling policies and investments for young children and families. ECE positively impacts on attendance, retention, and learning of children in elementary and higher education. The National Education Association recognizes that a high-quality early childhood program includes five, critical components: Provides a well-rounded curriculum that supports all areas of development

46 Addresses child health, nutrition, and family needs as part of a comprehensive service network Assesses children to enhance student learning and identify concerns Employs well-educated, adequately conversent teachers Provides small class sizes and low teacher-child ratios The U.S. Department of Education recognizes that the effectiveness of an early childhood program is dependent upon a number of factors: A quality staff An appropriate environment Consistent scheduling Parental involvement Proper grouping practices This federal agency also recognizes additional characteristics of a high-quality early education program: A balance between individual, small group, and large group activities A balanced schedule that does not result in rushed or fatigued children A clear statement of goals and a comprehensive philosophy that addresses all areas of child development A strong foundation in language development, literacy and mathematics. Access to a safe, nurturing, and stimulating environment, along with the supervision and guidance of competent, caring adults Engages children in purposeful learning activities and play, which is instructed by teachers who work from lesson and activity plans Nutritious meals and snacks Teachers and staff who regularly communicate with parents and caregivers Teachers who frequently check children's progress

2.3.2 Importance of Early Learning Research

into the human brain shows that the period from birth to the age of 8 is a critical phase for brain development and therefore the best time for learning. The

47 influence of the external environment is crucial to brain development. If a safe and accepting environment with abundant sensory stimulation is available in early childhood, children will have positive brain development which is beneficial to their future learning. According to the theory of multiple intelligences, there are many aspects of human intelligence and every individual has varied strengths. Pre-primary institutions should provide a diversified learning environment for children to develop their different potentials.

2.3.3 Need and Challenges in India

In India, according to Census 2011 data there are 164.48 million children of 0-6 years of age. Recognizing the need to provide quality pre-primary programmes, a number of constitutional and policy provisions have been made such as the 86th Constitutional Amendment which introduced Article 21 A on the right to free and compulsory education for 6-14 years old children and Article 45 to urge states to provide ECCE for all children until they complete the age of six years.

The Right of Children to Free and Compulsory Education (RTE) Act 2010

guarantees children their right to quality elementary education. ECE is not recognized as a compulsory provision by RTE, but RTE urges states to provide free pre-school education for children above three years. The 12th Five Year Plan acknowledges the importance of ECL and improving school preparedness. The Government of India approved the National Early Childhood Care and Education (ECCE) Policy in 2013. The Policy framework also includes the National Curriculum Framework and Quality Standards for Early Childhood Care and Education. The Policy caters to all children under 6 years of age and commits to universal access to quality early childhood education. The Ministry of Women and Child Development (MWCD) is the nodal department for ECCE. MWCD is responsible for the Integrated Child Development Services (ICDS) programme, which is a centrally sponsored and state administered [CCI: programme, covering around 38 million children through a network of almost 1.4 million Aanganwadi centres (a village courtyard). rCDS includes delivery of an integrated package of services such as supplementary nutrition, immunization, health check-up, preschool education, referral services and nutrition & health education. ECCE is one of the components and aims at psycho-social development of children and developing school readiness. Despite the recognition of the importance of ECE by the Government of India, the challenges in implementation still remain. There are still substantial numbers of children

48 not enrolled in preschools. Even in elementary education, while there is a significant rise in enrolments, the dropout rate continues to be a matter of concern, with drop outs being highest in the first two grades of elementary schooling. Learning assessments also show that literacy skills are poor in early primary grades. This points to the urgency of helping children, particularly from first generation families, develop adequate school readiness through a good quality ECE programme, to enable them to make a smooth transition. 2.3.4 School Readiness Program Children's School Readiness is affected by the early care and learning experiences they receive. The research in brain development emphasizes that early learning (especially from birth to five) directly influences a child's ability to learn and succeed in school. These studies have contributed to a growing awareness of the importance of quality early education and prekindergarten experiences. Research indicates that pre schoolers who attend high quality programs: Enter kindergarten with skills necessary for school success. Show greater understanding of verbal and numerical concepts. Are more socially competent. Show ability to stay with an activity longer. Are more likely to make typical progress through the primary grades. Are less often placed in special education classes. Are less likely to be retained in kindergarten. Children's readiness for successful transition into kindergarten needs to be viewed as a community responsibility. Parents, prekindergarten teachers, elementary schools, and local community programs working together provide the best base for children's success in school. Readiness needs to be defined in broad developmental terms so that the uniqueness of each child is preserved and respected. The National Education Goals Panel definition of school readiness covers three key areas: children's readiness for school schools' readiness for children family and community supports and services that contribute to children's readiness for school success

49 Five Essential Elements of School Readiness 1. Early Care and Education 2. Parenting and Family Support 3. Health and Social Services 4. Schools' Readiness for Children/School Capacity 5. Program Infrastructure, Administration and Evaluation 2.4 Early Childhood Education Curricular Domains 2.4.1 Social/Emotional Development Young children need social and emotional competencies. These skills are acquired through the development of close relationships, shared conversations and a nurturing environment. Preschool teachers guide children in learning social skills that include responsibility and self-control. Social emotional skills are developed through the shared activities of an appropriate and well designed preschool classroom environment. Preschool social emotional components are: Self-awareness and regulation Social emotional understanding Empathy and caring Initiative in learning Interactions with familiar adults and peers Group participation Cooperation and responsibility Relationship-attachment to parents, teachers and caregivers 2.4.2 Language And Literacy/English Language Development Children's early language growth and later language outcomes are directly related to the verbal communication children receive from adults and other children. In the preschool classroom, students have meaningful and comprehensive opportunities for language stimulation. Teachers embrace the primary language of the child while supporting the development of English

50 The key competencies for being ready for kindergarten and becoming fluent communicators and readers are as follows Language and Literacy 1. Language use 2. Vocabulary and grammar 3. Concepts about print 4. Phonological awareness 5. Word and letter recognition 6. Comprehension and analysis of age appropriate text 7. Literacy interest and response 8. Writing Categories of English Language Development Listening Speaking Reading Writing 2.4.3 Science Science in preschool fosters a joy of discovery and a positive approach to learning. Children become confident learner identifying solutions and problem solving through persistent hands on experimentation cum critical thinkers for lifetime. The content of Science in preschool consists of: The skills and language of science/scientific inquiry Knowledge of Physical Sciences, Life Sciences, and Earth Sciences 2.4.4 Mathematics Young children explore the mathematic domains through interactions with their everyday environment. Children experience mathematics through the daily routine by counting, sorting, building shapes, measuring, and estimating. The preschool classroom is designed with intention and order to promote mathematics experiences as the children play and explore their world. There are five main developmental mathematics strands:

51 Number sense Algebra and functions (classification and patterning) Measurement Geometry Mathematical reasoning

2.4.5 Visual And Performing Arts The visual and performing arts are natural to young children, exhibited early in the form of scribbling, pretending, humming, and swaying to music. In the preschool classroom, we engage and encourage children in arts activities on a regular basis. These activities lay the foundation and help children for successful learning Arts experiences are more about process than product Arts are inclusive and common to all Cultural competence and appreciation of the arts Artistic thinking processes and problem solving Learning through dramatic and active play Aesthetics in the classroom and intentional environment design Disposition of learning and meaningful connections to the world

2.4.6 Social Studies Children learn early how people live in the social world. Their preschool classroom mirrors the larger society with its diverse ethnic, religious, and socioeconomic backgrounds. Preschool teachers help children to think about themselves and their roles and responsibilities that they and others assume. Children are developing a sense of belonging to places and groups that are meaningful to them. They learn about the time and how their current experience is affected by their personal past and relates to their future The components of Social Studies in preschool are: Sense of time (history) Sense of place (geography and ecology) A preschool community member (civics)

52 Self and society Market place (economics) 2.4.7 Focal Areas of Development in Early Childhood Education Program

The early childhood years are filled with staggering growth and development. There are four main areas of development that occur all at the same time: Physical development: In the first years of growth young children are physically developing at a rapid pace. There is both gross motor (crawling, walking, running) and fine motor development (eye-hand coordination, hutting, writing, weaving) happening all at once. Social development: Understanding how to communicate, sharing, making friends, and getting along with others is just the tip of the iceberg when it comes to social development in the first five years of life. Emotional development: The building blocks for a positive self-esteem and self-confidence starts in early childhood. Young children are also learning how to cope and appropriately express their own emotions such as fear, sadness, anger, and happiness. Social and emotional development often comes hand in hand since how a child copes socially often impacts his or her emotional well-being. Cognitive development: Young children are always processing information about their world. They do so through both structured and unstructured activities, play, and by interacting with others. From experiences such as these, young children develop their understanding and abilities in the areas like mathematics, science language, art. The mind of a young child absorbs information like a sponge.

2.5 Curriculum Domains for Early Childhood Education and Sensory Mechanism 2.5.1 Principles for Designing Early childhood Education Curriculum We should adopt the following principles for designing the early childhood education curriculum. All children are capable of learning. The curriculum should be designed with a child-centred approach and from the children's perspective. It should be geared to meet their abilities, needs, learning styles, experiences and interests.

53 a. Curriculum should meet children's developmental needs and abilities: When designing the curriculum, institutions should identify children's best learning moments to meet their developmental needs and abilities, and provide them with sufficient space for a balanced development. b. Curriculum should relate to children's experiences and interests: Children's previous experiences influence their learning. Curriculum planning should therefore be based on childrens' experiences and should relate to the environment in which they live. In addition, the curriculum should be interesting, so that the children are self-motivated and ready to take an active role in learning. c. Curriculum should cater for children's holistic development in the cognitive, language, physical, affective, social and aesthetic aspects: Cognitive, language, physical, affective, social and aesthetic developments are interrelated and interwoven. Therefore, in the process of curriculum planning, due consideration should be given to children's overall development, so that individual developmental needs will be met in a comprehensive and well-balanced manner. d. Curriculum should foster children's knowledge, skills and attitudes in different learning areas: A pre-primary curriculum should take into account all six learning areas and the relevant concepts, skills and attitudes. e. Play may be a learning strategy: Children loves to play, which enables them to enjoy the freedom and fun of sharing and working with others. They learn effectively in a pleasurable atmosphere. Play is also one of the most effective ways of learning, since it enables them to express their inner feelings and explore the real world. Therefore, pre-primary institutions should incorporate play activities into different learning areas and plan the curriculum through an integrated approach.

The curriculum must address the following interrelated domains of holistic development through an integrated and play based approach which focuses on development of life skills.

Physical and Motor Development: Gross motor skills; coordination of fine muscles with dexterity; eye hand coordination; sense of balance, physical co-

54 ordination,

and awareness of space and direction; nutrition, health status and practices. Language Development: Listening and comprehension; oral skills/speaking and communicating; vocabulary development; pre- literacy/emergent literacy skills like

phonological awareness; print awareness and concepts; letter-sound correspondence; recognition of letters; building words and sentences and early writing.

Introduction to language of school transaction. Cognitive Development:

Development of various concepts including pre number and number concepts and operations (knowledge and skills related to comparing, classification, serialization, conservation of space and quantity, one to one correspondence; counting); spatial sense; patterns and estimations in measurement; data handling; skills related to sequential thinking, critical thinking, observing, reasoning and problem solving;

and knowledge about concepts and physical, social and biological environment. Socio-Personal and Emotional Development:

Development of self-confidence; self-control; life skills/ self-help skills; habit formation; initiative and curiosity; engagement and

persistence; cooperation; compassion; social relationships; group interaction; pro- social behaviour; expressing feelings, accepting others feelings . Sensorial

Development: Development of the five senses through visual, auditory and kinaesthetic experiences .

Development of Creative and Aesthetic Appreciation:

Exploring different art forms, develop dispositions, expression and appreciation for artistic, dance/ drama and musical activities 2.6

Sensitization of Family, Involvement in Pre-school and Primary Level 2.6.1

Family Involvement and Sensitization Family involvement means that families work together with caregivers and teachers to create an atmosphere that strengthens learning both at the program and at home. Parents should be sensitized to the importance of preschool education and its vital role in children's lives. Parents should also be made aware about the importance of play way approach in early childhood education. The planners and school personnel should focus on child centered curriculum for the growth and all round development. There should be participation and involvement of parents in early education to improve the

55 performance and the best out of child. There should be proper comprehensive supervision of Aanganwadi workers so that they dedicate more time to preschool educational activities. Emphasis should not be laid only on nutrition and immunization but children should also get adequate educational inputs. The preschool education component should be strengthened by providing training and orientation to Aanganwadi workers. Necessary educational equipment and toys should be available to each centre. There should be greater community participation so that every single person comes to know about ICDS and its widening coverage. People should treat ICDS programme as their own programme so that the impression that everything is to be done by the government only is changed. Understanding the concerns of parents of children with disabilities is an important step to school counsellors as they are the advocates for students with disabilities and their parents. "When schools and families work together, children have a much better chance for success, not just in school, but throughout life" (Henderson & Berla, 1996, p. 1). The benefits for children may look like they are too broad for your thinking about young children because they generalize across a wide age span (BCE to high school).

But if you keep in mind that the patterns for success begin in early childhood, the benefits have much relevance for work with young children. Those benefits of family involvement include: Higher grades and test scores Better attendance and more homework done Fewer placements in special education More positive attitudes and behavior Greater enrolment in postsecondary education 2.6.2 The Importance of Parent Involvement in Early Childhood Education Parents who are

involved in their child's education create a connection between the home and school. Those who participate along with their child are privy to the many aspects of their child's day. At home, they are able to replicate and extend activities that their child experiences in school. An astute parent will pick up where the school left off and have an intuitive sense

56 for what their child may need to work on to increase his competency and confidence. Ideas gleaned from the classroom give the parent inspiration for home activities that coincide with classroom tasks. Involved parents learn the names of various children in their child's class. They have a sense of who their child's friends are, who may be causing them trouble and how their own child is getting along in the group.

57 2.6.3 Framework for Accessible Family Involvement One comprehensive perspective on family involvement in preschool and primary evolved from a review of studies from preschool through high school that included educators and families (Epstein, 2001). Epstein's framework includes six types of involvement: Parenting-home environments that support achievement Communicating-two-way information sharing between school and home Volunteering-helping with planned activities in and outside the classroom Learning at home-parents assisting children in the learning process at home Decision making-parent involvement in school decisions. Collaborating with the community-use of local services and resources to help children learn. 2.7

Implication of Pre-school and Primary Levels for Intervention, Documentation, Record Maintenance and Report writing 2.7.1

Meaning and Importance of Record Keeping Records are the documented information generated, collected or received in the initiation, conduct or completion of an activity and that comprises sufficient content, context and structure to provide proof or evidence of the activity. Specifically, Hrach (2006) defined school record as a unified, comprehensive collection of documentation concerning all services provided to a student which may include intake information, evaluation(s), assessment(s), release of information forms, individual learning plan, all written notes regarding the student, all collateral information regarding the student, etc. Chifwepa (2001) observed that a record is a documented proof of transaction and that information is what a record contains, stores and transmits. Hence, records do not only enable school administrators to have a clear picture of what is available and what is required, they provide justification for certain needs and seem to extend the memory by which persons and/or organizations can pass on their culture and achievement to the future generation. In fact, the content and quality of school record (such as lesson plans, report cards, etc.) can serve as a direct reflection of the amount of work that has been expended on the school enterprise. Also, records help school administrators and parents to keep a concise and accurate timeline of events in the life of the pupils. Individuals may think they will be able to recollect past events, but it is easier to use a written record.

58 2.7.2 Why Do We Record And Document Observations? The typical day of a teacher is filled with multiple tasks, decisions and emotions. At the end of a week it is difficult to remember a comment made by a child on Monday about block building, or a problem solved by two children on Wednesday using their words instead of their hands. So recording is necessary. Teachers may feel recording takes precious time away from the children or necessary classroom tasks. However, when the process of observation and recording is organized systematically, it becomes an invaluable planning and teaching strategy. 2.7.3 Report Writing Writing a Report reflects the partnership among families and service providers and are guided by the families' priorities, questions, and concerns. Reports present a shared vision of the child, convey useful and understandable information, and maintains a balance among consumers' needs unique to each child. This process helps educators (in partnership with children, families and other professionals) to : plan effectively for children's current and future learning/wellbeing communicate about children's learning and progress/wellbeing and development determine the extent to which all children are progressing in their learning outcomes and if not, what might be impeding their progress identify children who may need additional support in order to achieve particular learning outcomes and provide that support. or assist families to access specialist help evaluate the effectiveness of learning opportunities. environments and experiences offered and the approaches taken to enable children's learning/wellbeing reflect on pedagogy that will suit the context and children. 2.8 Let us Sum Up 1. The National Education Association recognizes that a high-quality early childhood program includes five, critical components: Provides a of children curriculum that supports all round of development. Addresses child health, nutrition, and family needs as part of a comprehensive service network

59 Assesses children to learning and identify concerns Employs well-educated and well conversant teachers Provides small class sizes and low teacher-child ratios. 2. Research on human brain shows that the period from birth to the age of 8 is a critical phase for brain development and therefore, the best time for learning. The influence of the external environment is crucial to brain development. If a safe and accepting environment with abundant sensory stimulation is available in early childhood, children will have positive brain development which is beneficial to their future learning. 3. The Right of Children to Free and Compulsory Education (RTE) Act 2010

guarantees children their right to quality elementary education. ECE is not recognized as a compulsory provision by RTE, but RTE urges states to provide free pre-school education for children above three years. The 12th Five Year Plan acknowledges the importance of ECE and improving school preparedness. The Government of India approved the National Early Childhood Care and Education (ECCS) Policy in 2013. The Policy framework also includes the National Curriculum Framework and Quality Standards for Early Childhood Care and Education. 4. Five Essential Elements of School Readiness Early Care and Education Parenting and Family Support Health and Social Services Schools' Readiness for Children/School Capacity Program Infrastructure, Administration and Evaluation 5. Records are the documented information generated, collected or received in the initiation, conduct or completion of an activity and that comprises sufficient content, context and structure to provide proof or evidence of the activity. 2.9 Check Your Progress A.1. Describe about the curricular domains of pre school education. 2. Discuss about record maintenance and documentation. 3. Write about the significance of Early Childhood Education.

60 B. Assignment and Activities Discuss about the importanc of EarlyIntervention. Frame a curriculum for pre school children.

C. Points for Discussion / Clarification After going through the Unit you may like to have further discussions on some points and clarification on other. 1) Points for Discussion

When considering educational curriculum content for students with disabilities, it is important to recognize that the population of students labelled "disabled" is enormously diverse. For example, when a student has a physical disability alone, with no concurrent cognitive disabilities, it is generally accepted that he or she should pursue the full general education curriculum established for students without disabilities. Similarly, students with mild learning disabilities also are generally expected to pursue much, if not all, of the general education curriculum. So, for many students with disabilities, the question is not what these students should learn, but rather how they will access the curriculum and what accommodations will be needed. Decisions about curricular selection become more complex and the curricular content tends to be more individualized when students have more severe disabilities or have combinations of physical, cognitive, sensory, or behavioral disabilities. A quality curriculum for a student with disabilities includes learning outcomes that are at an individually appropriate level and are pursued within typical class activities (e.g., small cooperative groups, unit-based projects). Selecting appropriate learning outcomes has long been, and continues to be, considered a marker of educational quality for all students. Individually determined curricula for students with disabilities should include a small set of family-selected priorities to establish a focus for instruction, as well as a breadth of curricula that allows the student opportunities to explore many options that coincide with state or local standards. Curriculum planning for the intellectually disabled must be forward looking, giving due consideration to the students' current and future needs, sensitive to the environments in which the individuals would ultimately be expected to adapt and function after leaving school.

64 3.2 Objectives
After going through this unit you will be able to

Discuss the different curricular domains in secondary level. Discuss the significance of pre vocational education. Discuss the importance of vocational education. Discuss about the different domains of pre vocational and pre vocational curriculum. 3.3 Curriculum Domains at Secondary Level 3.3.1 Meaning and Definition of Curriculum Curriculum is the base in education on which the teaching learning process is planned and implemented. It is the totality of all the learning to which students are exposed during their study in the school, in the classroom, in the laboratory, in the library, in the workshop, on the farm and the playground. A curriculum planned as a comprehensive design for learning, contributes a basis for the growth of human being and growth of community (Phenix, 1964) The term curriculum has been derived from a Latin word "Currus" meaning a 'chariot' or 'runway'. It resembles closely to the Sanskrit term 'karyakram' and English term 'course'. Basically it is the programme of various activities and experiences of learning conducted by a body/institution for the benefit of the student's present and future life. Curriculum does

not mean only the academic subjects traditionally taught in school, but it includes totality of experiences that a child receives at school. 3.3.2

Approaches to Curriculum Development Unit Approach Unit approach was introduced by Ingram (1935) later popularized by Meyen Centre upon development of life experience units including the six major core areas of arithmetic, communication, health, socialization and vocation. This was recommended for group teaching of children with special needs as each~elected life experience units is carried out by a group which in itself is a learning experience. This approach suggests an in built evaluation system, but requires elaborate planning on the part of the teacher.

65 As children with intellectual disability learn better through experiences, unit approach is found suitable as it has life experience units as the focus. System Approach System approach is defined as deliberately designed synthetic organisms comprised of interrelated and interacting components which are employed to function in as integrated fashion to attain pre determined purpose (Benathy, 1968). The steps include "SOME" system which is briefly explained as S- Survey of the variables including all assessment details. O- Setting Objectives. M- Multi 'M' program variable such as motivation, methods, materials, modality and models of learning. E- Evaluation This approach also takes into account the pupil teacher- learning situation and their interaction with family, community, administrative arrangements, therapeutic supports and legal aspects. Thus this approach provides a unified systematic way for developing curriculum to a special teacher. This approach is in many ways similar to the behavioral approach which is popularly in use in recent years. In this approach the common curricular content is not specified. Based on the assessment of the child, the teacher has to develop suitable content of each child. Child Centered Approach A child is to be prepared for life. But this does not mean that his immediate interest should be sacrificed for the sake of future which is indefinite. As Ryburn (year?) puts, "the best preparation for the life that we can give a child is to help him to live fully and richly his life at that stage at which he is." The child automatically prepares himself for the next stage by living well and truly life at one stage. Smith and Harrison (years?) also observe "Education regards the child as an individual growing by his own activity, living in his own environment, and preparing himself for adult life, not by imitating the adult, by living as fully as possible in the environment of childhood possible. The basis of "Child centered curriculum" is that every individual is unique; each child is different having individual needs. Learning pace and ability depends on the child's ability, interest and aptitude. This approach aims at developing the deficient skills in the child making him achieve the optimum level of functioning. According to the needs and abilities learning experiences are provided. No task or activity is part of the content unless is 66 wanted or needed by the child. The method of teaching and aids for learning also depends on the child's ability, interest and aptitude. Ecology Based Approach The current trend in curriculum development for the children with intellectual disability is the ecology based approach. This approach stress the importance of curricular items based on the environment in which a child lives. Instead of the 'watered down curriculum' of regular education, this approach gives emphasis on the inclusion of those content areas necessary for independent living in his environment. This includes the assessment of not only the abilities of the child, but also his environment, the activities of the 'non handicapped' people in 'that' environment on a daily, weekly and occasional basis. This would lead to the process of decision making on what the child,— Can already do, What can be done by him with training and / or adaptation? What he

is the child's need. When such a clear concept is developed, decision making on curriculum areas to be taught and what is best suited to his community becomes easy. In addition, one can be sure that what is taught will have utility value as it is absolutely functional. Popularized by Ben (1988), this approach is implemented in many countries, especially in developmental countries with varied socio-cultural practices. When the content for the curriculum is decided using this approach, the process recommended for implementing the curriculum is development of activity based IEPs. Instead of focusing on skill areas, the 'activities' cutting across various skill areas of self-help, social, motor, language, academic, vocational and so on are selected and the IEPs are developed to achieve the independence in the given activity. By this, measuring progress becomes easy and as selection of activity is need based and functional it will be performed by the child. In other words, retention of the learnt skill is maximized by regular performance.

Task Analytic Approach This approach described by Hewett (1967) creates an hierarchy of educational tasks ranging from attention level to an achievement level of performance. This hierarchy provides framework for organizing the structure of the class, content, materials and rewards leading to meaningful transaction between the teacher and the student at the child's readiness level. The curricular items thus selected are broken down into tasks and each task is analyzed in a sequential manner for teaching the child. This breaking down of tasks to teach the child has the advantage of analyzing errors and correcting them.

67 Social Learning Approach This is an interaction model of environmental encounters designed to develop 'critical thinking and independent action' among children with intellectual disability (Glodstein, 1969). This approach takes into consideration the child's expanding world from self to home and family, neighborhood and community. The curricular items are selected keeping in mind the required competency of the child to function independently at each level. Psychological, physical and social aspects of the child are identified as need areas for the above environmental components and for each stage the required communication) art and quantitative thinking are incorporated in the curriculum. This approach has many advantages.

3.3.3 Curriculum Domains at Secondary Level This group includes children in the age group of 11-14 years. In this group the students are trained in their basic self-help skills, language, cognitive, academic and co-curricular activities in a more structured form. Music, Dance, Art & Craft, and Yoga form an integral part of their curriculum. Speech therapy, occupational therapy, behavior modification are also provided simultaneously with the main learning schedule of the children.

3.3.4 Functional Curriculum for students in the secondary group Students with intellectual disability in the secondary group need a distinct curriculum; a curriculum geared towards meeting the specific needs of this particular population. Smith and Smith (1978) proposed a curriculum be devised for each special education program that is practical and targets the skills needed for independence of the population within particular programs. Components of a functional or life management curriculum include the functional applications of core subject areas like academics, vocational education, community access, daily living, financial, independent living, transportation, social/relationships, and self-determination (Patton, Cronin, & Jairrels, 1997).

68 A distinct curriculum for students with intellectual disability at secondary level is geared towards their goals is not far from what exists in Western Schools today. In schools and some preparatory secondary schools, students are prepared and taught subjects, knowledge, and skills geared directly towards their post school life; knowledge that will enable them to be successful in the adult world. This same opportunity should be available for students with intellectual disability at secondary level. A separate, unique curriculum is geared towards the different needs of a particular population. For example, functional mathematics does not just refer to basic skills, but also to more everyday computation and problem solving skills, which are embedded into experiences of individuals with mild mental retardation might encounter in life (Butler, Miller, Lee, & Pierce, 2001). Researchers stress the daily use of mathematics, regardless of one's mental capacity. Some degree of math proficiency is required for most jobs and therefore, special educators need to devote attention to teaching functional math skills that are applicable on the job, at home, and in the community (Patton, Cronin, & Bassett, 1997).

3.4 Curriculum Domains at Pre Vocational Level Children with intellectual disabilities may not be able to go through the regular educational system that prepares them for careers and jobs. They may not be able to cope with high school or college.

3.4.1 Areas of Preparation at Pre vocational Level Some of the aspects that are covered in pre vocational training for students with intellectual disabilities are:

Functional Literacy: Children may require training in basic literacy. Sight reading, identifying their name and writing it, identifying and writing their address are some of the tasks.

Functional Math: Children will require training in simple calculations, use of a calculator, counting, sorting, arranging in numerical order etc. Skills in weighing and measuring are also very useful.

Work behaviors: Children will require training in producing neat and quality work, punctuality and regularity, reporting once a task is completed, correct use and maintenance of tools and other materials.

69 They also need to know and learn about the behavior that is expected at the workplace. Social skills: Children need to learn to relate to their supervisor and colleagues, ask and answer questions and build relationships with others. In addition, the child must be taught to accept criticism from the supervisor and to express frustration in an acceptable way. Exposure to different occupations and work tasks: While preparing for employment, the child must be exposed to a variety of work tasks. This will help teachers and family to understand more about the aptitude and skills of the child.

3.4.2 Focal Pre-Vocational Skills 1. Understand and accept 'work times' and 'relax times' of day 2. Sustain attention to tasks (at least 15 minutes) 3. Independently recognize feelings of anxiety, frustration, and anger in self 4. Do non-preferred tasks without complaining/arguing/negotiating 5. Ask for help 6. Follow multi-step directions (out of sight of a prompter) 7. Be comfortable with getting temporarily interrupted 8. Accept suggestions/corrections 9. Read time on a variety of clocks/watches/phones 10. Understand various forms of authority 11. Regularly demonstrate semi-professional social niceties 12. Attend to personal cleanliness/hygiene, including dress code 13. Explore self-awareness: understand/accept diagnosis, learn about accommodations, strengths and challenges. 14. Disclose diagnosis (if desired) 15. Make small decisions independently 16. Demonstrate self-advocacy skills (indicating preferences, not waiting for prompts, making goals, asking for accommodations)

70 17. Demonstrate safety skills in the community (strangers, unwanted advances, emergencies) 3.5 Curriculum Domains at Vocational Level 3.5.1 Importance of Vocational Curriculum Two key legislative acts that address workforce preparation of students are the Carl D. Perkins Vocational Education Act and the Individuals with Disabilities Education Act (IDEA). The purpose of the Perkins Act, is currently in the process of being reauthorized, is to provide technical training and education to students who do not necessarily plan on going to college. The act requires schools to provide parents and students with: Vocational education opportunities, which should be offered to the student by the beginning of ninth grade or one year before the student enters the grade in which vocational education is offered. Eligibility requirements for enrolling in vocational education. In addition, students with disabilities are entitled to receive. An assessment of interests, abilities, and special needs as well as other special services designed to help students enrolled in vocational education transition into post school employment or training . Career assessment, planning, training, and school-to-work transition services. IDEA requires schools to provide services to students with disabilities that will help them make a successful transition from school to post school activities-such as work, continued training or education, and other aspects of community living. By age 14, a student should have a transition plan incorporated into their IEP that specifies what services the student needs to make a successful transition from high school to work and community living, what career activities the student should undertake, and who will be providing the required services. 3.5.2 Focal curriculum of

Vocational Education Vocational training should provide students with a curriculum that prepares them for the job that they intend to enter. Broad-based knowledge and skills are good, but for some

students with disabilities, specific skills are necessary for survival In the workplace and In the community and need to be explicitly taught.

71

Academic Skills Reading and writing (e.g., sight-word vocabulary, spelling, handwriting, typing, etc.) Math (e.g., basic computation, money, measurement) Problem solving Listening comprehension Speaking Computer Art or music Communication Skills Following and giving directions accurately Communicating information Understanding and processing information Requesting or offering assistance in

Social and Interpersonal Skills Answering the phone and taking a message Making necessary phone calls to employers and other professionals as a part of a job requirement Displaying appropriate work behavior and etiquette Knowing appropriate topics for discussion in the workplace Learning how to protect them from victimization Learning social problem-solving techniques Occupational and Vocational Skills There are a number of skills and behaviors that most, if not all, jobs require. It is important to help students

who do not possess these skills, to acquire them. Examples of these activities include the following: Using a time card and punch clock Arriving to work on time Calling when sick

72 Requesting vacation time Using the appropriate tone of voice and volume Accepting instructions and corrections Knowing appropriate interaction with co-workers (i.e., getting along; social problem solving; making friends; and recognizing personal, professional,

and sexual boundaries) There are also a number of skills that students should have so that they can be as independent as possible in their future job searches;

these skills include the following: Looking for jobs (advertisements in the newspaper and online, help from neighbours and local resources) Filling in job applications Writing resumes and covering letters Enclosing necessary identification (photo ID, birth certificate) etc. Having for appearing in the interview skills. 3.6 Rehabilitation of PWIDs Under National Skill Development Scheme (NSDS by MSJ&E) 3.6.1

Background The National Policy on Skill Development was first formulated in 2009, and it has provided the framework for skill development activities in the country. Over the past five years, changes in the macro environment, and the experience gained through implementation of various skill development programmes in the country have necessitated changes in the policy. The creation of the Ministry of Skill Development & Entrepreneurship as the nodal Ministry for all skill development activities across the country has led to changes in the Allocation of Business Rules that have further necessitated the process. The new policy reflects the tenets of the-Skill India programme of the Government, which focuses on outcomebased approach in terms of providing meaningful employment in the form of both wage and self-employment. Accordingly, the National Skill Development Policy, 2015 is being formulated, and it will supercede the Policy of 2009.

73 3.6.2 Vision of the National Policy on Skill Development The overall vision of the policy is an integrated outcomes-based skills development eco-system, which would promote economic, and employment growth and social development through a focus on education, skill training and employment services. The Skill India Programme is a commitment to the overall human resource development of the country. The basic tenet of the National Policy on Skill Development would be the development of the individual. The emphasis of the policy is to deliver skill development so that it empowers the youth to attain decent standard of living. However, in order to link these two elements measures that adhere to good quality standards of the skill development programmes should be adopted. There is a need to facilitate a general increase in the skills profile of the population, through accredited high quality education and training linked to the National Skills Qualifications Framework (NSQF), a competency based framework. The NPSD envisages creating a vibrant educational and skill ecosystem which would make our country the "skill capital of the world". It seeks to make skill development an integral part of all development schemes and aims to address the employability issue by initiating a multi-skills development programme in a mission mode with focus on job creation and entrepreneurship, in both rural and urban areas covering all socioeconomic groups of the population. The policy identifies the strategic interventions required to meet the objectives of skilling the youth of the nation as it has become imperative to India's sustained growth and is no longer a matter of choice. The policy recognizes that the need of the hour is to create a skill eco-system with increased investment. The skill policy also envisages harnessing inclusivity and focusing on equity -- both social and gendering equity. There is need for affirmative action in accordance with Constitutional provisions to ensure that persons belonging to the Scheduled Castes, Scheduled Tribes, Minorities, Women, and other disadvantaged groups are provided the opportunity to develop their skills. The skill policy would also focus on training to promote self-employment and focus would also be laid on special training on entrepreneurship. The NPSD would also focus on increasing the relevance with future employment market including promotion of self-employment; soft skills and entrepreneurship skills will be made integral part of skill development.

74 3.6.3 Scope of the National Policy on Skill Development The issues which the National Policy on Skill Development & Entrepreneurship seeks to address include the following: Changing the negative perception associated with vocational education and focusing on mobilization of candidates on the same: A major challenge in the skills arena is the mobilization of candidates, partly because of the socio-cultural attitude towards blue collared jobs. It is also evident that lack of awareness is a major reason for the relatively poor response to skill development opportunities. The skills! policy envisages awareness generation and information dissemination on the part of all the implementing agencies be it the Central Government, state government or the private agencies. A major initiative would be made in creating and raising awareness among the target groups about the benefit of skill development, employment and learning opportunities and also about support schemes that enable them to participate in training. Co-ordination and integration of all skilling efforts in the country: A large number of stakeholders-ranging from central and state Governments, ministries, training providers, assessment agencies, industry bodies, and workers- are involved in the skill development space. Co-ordination amongst these various stakeholders often results in shortfall in implementation. Furthermore, the lacunae in establishing a clear skill supply- demand paradigm also limit positive impact in the resultant employment and productivity of the markets. Hence the NPSD envisages achieving effective coordination mechanisms at various levels. Outcomes approach focusing on both employment and employability: When viewed from the perspective of a trainee, the ultimate goal of any skilling exercise is to ensure socio-economic mobility. Better employment opportunities for the trainees are an effective way to gauge the effectiveness of any skilling initiatives. This can be measured in terms of a trainee's ability to move from the informal sector to the formal sector and/ or a raise in remuneration post, etc. Employability- as demonstrated through skills of an individual- is intrinsically linked to achieving gainful employment. From the perspective of the employer, the prospective trainee/employee must deliver tasks assigned to him/ her efficiently. The ability of an employee to perform tasks effectively rest on his mastery over the job, which may relate to both core and soft skills. Thus, key objective of the policy is to enhance employability so that it reflects on employment of trainees. Improving the capacity and quality of Training Infrastructure, along with geographical and distribution of capacity, sector wise and geography wise: Though the capacity that had been created by the private sector in the country is unknown, it is 75 evident that the infrastructure is skewed in terms of both sector and geography. A survey could be conducted to know the capacity that already exists and how it is being utilized, so that the shortfall in capacity can be gauged and a plan for meeting this shortfall can be formulated and implemented. The objective of enforcing quality and relevance in skill development will also be realized through improving infrastructure, improving quality of trainer and developing National Skill Qualification Framework. Quality assurance and linkages with the NSQF: Ensuring the quality of training is essential for all stakeholders within the skill ecosystem and the resultant certification is a validation and recognition of the same. Irrespective of source of learning, whether through formal or informal or on-the-job learning, the quality assurance against certain benchmarks will facilitate recognition of learning. The NSQF is an important institutional mechanism that ensures consistency of nationally recognised qualifications both for formal and non-formal skills based education and training. It accommodates experiential life-long learning through mechanisms such as recognition of prior learning, improves the alignment of formal and non-formal training programs with industry requirements; and increases options for students by broadening program and progression for learners through horizontal and vertical pathways. Working closely with the private sector and the industry: Industry is an essential partner in skill development, and there is need to encourage greater participation from the private sector. In India the initiative of developing skills has largely been a Government driven exercise. However, as a stakeholder, that will eventually absorb all the skilled manpower, the industry has an equal responsibility to participate in the skilling campaign. Successful models across the globe have indicated that inputs from the private sector should be at multiple levels of the skill value-chain, ranging from inputs to market information, to designing of occupational standards, to investment through apprenticeship and re-skilling to ensure trained manpower. Thus, a greater emphasis will be placed on the industry participation in the new policy. Third party assessments and Certification: For meaningful skill development, there is a need for an independent and good quality third party certification, which would be adopted by institutes imparting skill development programmes as a means to bring accountability and regulation over training and assessments. This would promote professional and personal development of individuals. Apart from the formal sector, a large number of workers in the informal/unorganized sector have acquired skills through experience or other non-formal learning channels that are not able to derive proper market value for their services. The NSQF would facilitate certification to such persons to help them move into the formal sector jobs as long as they are able to perform to the

76 outcome standards. This recognition of prior learning would empower millions of workers through formal recognition of their skills. Address the special needs of difficult areas — NE, Hill States, LWE affected areas: The border, hilly and difficult areas, including the North-Eastern states, J&K, and the hilly forested areas of central and eastern India, face additional challenges arising out of inadequate infrastructure, poor investment and industrial opportunities. Special attention needs to be given to the youth residing in these regions to address their needs for employment and employability. In order to provide more equitable access across the country, special efforts will be mounted to establish training facilities in deficient regions. Technology interventions in terms of LMIS and monitoring of outcomes: There is a strong necessity to design platforms that facilitate information exchange and mitigate information asymmetries. The labour market information system will be dynamic platform that will enable a range of stakeholders to access reliable information. In line with the national policy, it will retain trainees as the focal point of initiatives; however, it will also cover a range of stakeholders such as training providers, industry/employers, Government agency/policy makers, Assessment agencies, Certifying agencies, Funding agencies, International Agencies, Sector Skill Councils, Labour Market tracking agencies, Govt. & Private agencies. The information generated under such a system would be both quantitative and qualitative in nature. Furthermore, the aim of the system will be to accumulate data through varied sources that will be analyzed to suggest corrective measures and forecast trends that will be linked to broad national development strategies, so that new and existing employment prospects and their skills requirements can be identified. International equivalence and mobility of skilled manpower: The objective of the current exercise of skill development is not only to meet the domestic demands but also international markets. In a competitive global economy, trained manpower is an asset for employers, where an individual's skills must be a reflection of quality and competitiveness. The policy seeks to create avenues for greater mobility through quality assurance measures that will be at par with international standards. To this end, recognition and portability of skills abroad is an important outcome of the policy. Create opportunities for all to acquire skills throughout life, and especially for youth, women and disadvantaged groups: High inclusivity is one of the central visions of the NPSD. The NPSD envisages skill development initiatives that will harness inclusivity and reduce divisions such as male/female, rural/urban, organized/unorganized employment and traditional/contemporary workplace. One of its key objectives is to

77 ensure that the skilling needs of the disadvantaged and the marginalized groups like SCs, STs, OBCs, minorities, women and differently abled persons, as well as those living in difficult geographical pockets, are appropriately taken care of. Develop a high-quality skilled workforce/entrepreneur relevant to current and emerging employment market needs 3.7

Implications of Placement for Inclusion in Community, Documentation, Record Maintenance and Report Writing 3.5.1 Implications of placement for inclusion

One of the most important principles of inclusive education is that no two learners are alike, and so inclusive schools place great importance on creating opportunities for students to learn and be assessed in a variety of ways. Teachers in inclusive schools therefore must consider a wide range of learning modalities (visual, auditory, kinesthetic, etc.) in designing instruction. Certainly this enhances the way in which educators provide supports and accommodations for students with disabilities, but it also diversifies the educational experience of all students.

Inclusive

education [or students with disabilities can only be successful when those students feel that they are truly a part of

the school community. In the past, special education often involved the segregation of students with disabilities for the purpose of specialized instruction. Not only does that model of special education in a separate setting deprive students with disabilities of interaction with their peers and full access to the curriculum, it can also involve duplicate systems and resources that are costly for schools to maintain. Inclusive education can make more efficient use of a school's resources by maximizing the availability of staff and materials for all students. The

curricular aim recommended is, 'To provide an education to equip students to live as independent a life as possible by them, in a community which may not always be fully cognisant of their needs.' The objectives to fulfil the desired aim should be: The realisation that sets and quantities are essential to spatial positioning (Maths). The protection and care for the environment around them (Science). The ability to communicate their needs (Language) and be aware that others also have needs to be met.

78 The awareness of being a part of the global family (History). The recognition that everyone is different but that there is a place for everyone (Social Studies). The ability to recognize that to be accepted by society one needs to contribute according to one's potential (Human and Commercial Geography). The primary need for self-care (Hygiene and Biology). The necessity to be selective in their faith in their fellow beings (Values). 3.7.2 Meaning and Importance of Record Keeping Records are the documented information generated, collected or received in the initiation, conduct or completion of an activity and that comprises sufficient content, context and structure to provide proof or evidence of the activity. Specifically, Hrach (2006) defined school record as a unified, comprehensive collection of documentation concerning all services provided to a student which may include intake information, evaluation(s), assessment(s), release of information forms, individual learning plan, all written notes regarding the student, all collateral information regarding the student, etc. Chifwepa (2001) observed that a record is a documented proof of transaction and that information is what a record contains, stores and transmits. Hence, records do not only enable school administrators to have a clear picture of what is available and what is required, they provide justification for certain needs and seem to extend the memory by which persons and/or organizations can pass on their culture and achievement to the future generation. In fact, the content and quality of school record (such as lesson plans, report cards, etc.) can serve as a direct reflection of the amount of work that has been expended on the school enterprise. Also, records help school administrators and parents to keep a concise and accurate timeline of events in the life of the pupils. Individuals may think they will be able to recollect past events, but it is easier to use a written record. 3.7.3 Why Do We Record And Document Observations? The typical day of an early childhood teacher is filled with multiple tasks, decisions and emotions. At the end of a week it is difficult to remember a comment made by a child on Monday about block building, or a problem solved by two children on Wednesday using their words instead of their hands. When the process of observation and recording is organized systematically, it becomes an invaluable planning and teaching strategy.

79 3.7.4 Report Writing Reports in early childhood reflect the partnership among families and providers and are guided by the families' priorities, questions, and concerns. Reports present a shared vision of the child, convey useful and understandable information, and strike a balance among consumers' needs unique to each child. This process helps educators (in partnership with children, families and other professionals) to: plan effectively for children's current and future learning/wellbeing communicate about children's learning and progress/wellbeing and development determine the extent to which all children are progressing in their learning outcomes and if not, what might be impeding their progress identify children who may need additional support in order to achieve particular learning outcomes and provide that support, or assist families to access specialist help evaluate the effectiveness of learning opportunities, environments and experiences offered and the approaches taken to enable children's learning/wellbeing reflect on pedagogy that will suit the context and children. 3.8 Let us Sum Up 1. The term curriculum has been derived from a Latin word "Curru" meaning a 'chariot' or 'runway'. It resembles closely to the Sanskrit term 'karyakram' and English term 'course'. Basically it is the programme of various activities and experiences of learning conducted by a body/institution for the benefit of the student's present and future life.

Curriculum does

not mean only the academic subjects traditionally taught in school, but it includes totality of experiences that a child receives

at school. 2. A

distinct curriculum for students with intellectual disability at secondary level is geared towards their goals is not far from what exists in Western Schools today. In schools and some preparatory secondary schools, students are prepared and taught subjects, knowledge, and skills geared directly towards their life post school; knowledge that will enable them to be successful in the adult world. This same opportunity should be available for students with intellectual disability at secondary level.

80 3.

Vocational training should provide students with a curriculum that prepares them for the job that they intend to enter.

Broad-based knowledge and skills are good, but for

some

students with disabilities, specific skills are necessary for survival in the workplace

and in the community and need to be explicitly taught. 4. The National Policy on Skill Development was first formulated In 2009, and it has provided the framework for skill development activities in the country. Over the past five years, changes in the macro environment, and the experience gained through implementation of various skill development programmes in the country have necessitated changes in the policy. The creation of the Ministry of Skill Development & Entrepreneurship as the nodal Ministry for all skill development activities across the country has led to changes in the Allocation of Business Rules that have further necessitated the process. The new policy reflects the tenets of the Skill India programme of the Government, which focuses on outcomes, based approach in terms of providing meaningful employment in the form of both wage and self-employment. 5. Records are the documented information generated, collected or received in the initiation, conduct or completion of an activity and that comprises sufficient content, context and structure to provide proof or evidence of the activity. 3.9 Check Your Progress A.1. Describe about the curricular domains of pre vocational education. 2. Discuss about record maintenance and documentation. 3. Write about the significance of Vocational Education. B Assignment and Activities Discuss about the importance of planning curriculum for children with intellectual disability. Frame a curriculum for pre vocational education. C Points for Discussion / Clarification After going through the Unit you may like to have further discussions on some points and clarification on other.

4.1 Introduction
The educational provision for students with special needs in India in the recent two and half decades is being focused on regular setting where they get equal educational opportunity as other non-disabilities peers which we call as integration, mainstreaming or inclusion. It has been described as the central issue in education for all. In inclusion, all students must have the opportunity to be enrolled in the regular classroom of the neighborhood school with age-appropriate peers, or to attend the same school as their brothers and sisters. When the children with disabilities are coming together with non-disabilities children in regular classrooms, certain adaptation in environment and curricular activities should be made. Developing curriculum for students with intellectual disability is a challenge. Due to their cognitive deficits each child needs a tailor made curriculum for him/her. When children are grouped together based on certain parameters, there is a need for curricular guidelines so that the curriculum is suitable to the group while taking into account the individual needs. In this unit, you will study about several aspects of curriculum adaptations.

4.2 Objectives After going through this unit, you will be able to

Understand the
Need

for curricular Adaptation, Accommodation and Modification.

86 Narrate the Adaptation, Accommodation and Modification for Pre-academic Curriculum. Narrate the Adaptation, Accommodation and Modification for Academics Curriculum. Narrate the Adaptation, Accommodation and Modification for Co-Curriculum. Narrate the Adaptation, Accommodation and Modification for School Subjects. 4.3

Adaptation, Accommodation and Modification in Curricular Activities

Curriculum adaptation tends to be significant at all grade level, but teachers have to develop their own style of presentation or teaching strategy, which may be related to

how they teach or the availability of instructional materials in schools. Presentations may include combinations of lectures, assignments, or a host of other teaching / learning approaches. Teachers do change their methods through the years, and some teachers may be so open to trying new approaches that they don't give the "old" approach a proper tryout. But it appears that many, perhaps most teachers tend to have established ways to teach the various subjects or skill they are assigned to teach with the consideration of needs of children. These innovative methods are certainly logical if these methods have proved to be effective for them. Before looking at curriculum adaptations for children with intellectual disability, let us understand the status of curriculum for children with other disabilities. It is important to understand the similarities and differences in developing curriculum for children with disabilities in general and for those with intellectual disabilities in particular. Curriculum decisions are founded on the beliefs and values regarding the purpose of education and the benefits of its outcome. Every curriculum aims at realizing the fullest potentials of students and helping them become productive and contributing members of the society. Need for Adaptation, accommodation and modification in curriculum When we look at children with disabilities, their abilities and needs are varied, demanding adaptation in curriculum content and transaction without compromising on the objectives and learning outcomes. As seen earlier, the purpose of education is the same for all human beings. The process

87 might vary based on individual profiles. Therefore, before planning curricular adaptations, we have to consider what can be common as in regular education for non-disabled children and what needs to be adapted. The common focus in schools is to develop competencies in Leading independent lives Developing and maintaining positive relationship with family and community Carrying out day to day activities in an acceptable manner and Being a good citizen Three important areas of consideration when dealing with students with disabilities are: 1)

how the curriculum is presented, 2) how students are required to respond, and 3) how their efforts are evaluated. Modifications in these three areas require advanced planning, and some require a degree of organization. All of these suggested adaptations will permit wider application, which indicates that all curricular areas at all grade levels are subject to some useful modification. Adaptations in instructional strategies are needed, and given much priority, so as to make it possible for the student to achieve goals that are determined by the teacher. As with all other accommodations, it is essential plan ahead special equipment's that are required. Teachers must think ahead on a daily basis - what is needed for all students with special needs. On a weekly, monthly, or unit basis - what additional materials, alternate books, and so on are needed. Specialists must help regular classroom teachers to organize the learning activities through appropriate instructional strategies. 4.3.1

Modified Instructions for children with intellectual disabilities (ID) The training programme for the children with intellectual disability tends towards the development of the adaptive behavior ranging from self help skills to the development of vocational skills.

The lesser the degree of disability the stress is on the development of self help and community living skills. The knowledge and skill regarding the individualize education programme is the basic to any training programme for the children will Intellected Disability. 1. Individualized training programme : The individualized training programme should be based on the assessment with reference to the academics, activities of daily living, social skills, personal skills, vocational skills and community skills. Plan for training is developed with objectives, strengths, and weaknesses. In functional academics, the academics are taught to the student to function independently on

88 with minimum help in his/her society. In functional reading, the person with Intellectual Disability is taught to read labels in grocery shops, names of stations, bus numbers, T.V. programmes, access the telephone directory to get certain phone numbers etc. Functional writing would entail writing ones name, address, telephone number, hand rudimentary banking, e.g., filling in deposit slips etc. Functional mathematics would teach him/her enough number work to make small purchases, handle change, travel independently and the concept of time, calendars and money. 2. Skill

Development: The specific skills to be developed among children with Intellectual Disability based on the extent of Intelligent Quotient (IQ). Sometimes Developmental checklist can be referred to get the profile of the child. A) Children with mild intellectual disability (Focus on academic skills and vocational training) -

The planned adapted educational experiences are given at four different levels. Pre-school level - Focus is mainly on daily living skills. Primary school level - reading, writing and social training (sharing, peer helping etc.) Intermediate classes - along with academic skills this group also needs pre- vocational training and training in independent living skills to live independently in society. Secondary school level - all vocational and social skills, interacting and coping with people at work place and in other settings.

B) Children with moderate intellectual disability - (Focus on development of self- help as well as adequate communication and social skills to allow for semi- independent living.

The planned adapted educational experiences are given in six areas. Self help skills Communication skills Personal social skills Perceptual motor skills Functional academic skills Vocational skills

C) Children with severe intellectual disability - Educational efforts mainly focus on basic communicational skills and self-help skills for children with severe intellectual disability. D) Children with profound intellectual disability - main training should be on their

89 daily living activities because of physical and intellectual limitations. The daily living skills are in the areas of physical development, self-care, language training (including training on Augmentative and Alternative communications) and social behaviours. Challenging Behaviours such as rocking, self-abusive behavior, head banging etc. are managed with the help of behavior modification techniques. 4.3.2 Organizing Adapted Materials The organization of teaching materials is important for all students including children with disabilities. But

students with disabilities may sometimes need materials that are different from those required by normal students. Most of the special teachers prepare learning activities to satisfy the educational needs of children with disabilities so that maximum educational benefit can be derived.

The use of 'Activity schedule' is one of the more common organizational practices in use. The activity schedule should be kept for easy reference. Students should be taught to refer the activity schedule and check instructions. Standard cards might be used that say, "Do THIS FIRST, DO THIS SECOND", and so on. They can be kept in the appropriate folders. Cards with numbers may be used. Picture cards may be used to indicate to do one assignment first, and then second, and so forth. Because some may have difficulty with instructions as to how to proceed, innovative teachers have developed unique symbols that indicate what to do. After the student learns to associate the symbol with a particular concept, this system can prove to be very effective, some students need only very few directional and or orientation skills that they must be taught accordingly. 4.3.3 Organizing Adapted Modified Instructional Process The teacher has to use the combination of instructional strategies to suit the educational needs of learners. i)

The teacher who prefers innovation attempts to elicit sorting, grouping, categorizing, and inductive thinking and promotes attention to goals, objectives, and logical sequential thinking. ii) The teacher who prefers lecturing describes, explains, illustrates, and asks students to recall or apply what was presented. iii) The entertainer - one who regularly digresses from subject matter - is open to student opinions and their self-expression and is not particularly goal oriented. iv) The role-learning teacher - one who provides information, repeats for emphasis, and expects students to attend, practice, and regurgitate.

90 v) The counselor - one who listens, redirects behavior,

and elicits student's feelings, attitudes and values. vi) The story teller - one who narrates, reads, tells that which is to be learned, and encourages sharing and participation in this process.

Most teachers reflect some combination of styles, and special education teacher must recognize these differences and provide assistance that complement existing styles. Planning is a prerequisite to effective teaching and that good planning can "extend the teacher's tolerance for stress, heighten sensitivity to student behaviours, and enhance openness to new techniques". Advance planning takes many shapes and forms, including ordering of new materials and equipment and other "standard" practices known to all organized, experienced teachers. For the special educator, this means that whenever possible, all available information of the students who will be part of the programme should be assembled and organized to provide a basis for determining what materials to be needed. The special teacher should know their academic needs, social/emotional needs, ability to work in a small group, personal interests, procedures that have worked most effectively in the past, and other related information. This information is in addition to information about age, physical characteristics, home/family status, home assignment, previous (standardized) testing date, and the like.

4.3.4 Adaptations in Evaluation Procedures For some teachers it is a matter of professional ethics, and adaptations in evaluation procedures may be viewed as a "lowering of academic standards". In thinking through the ethics of the matter, it may be of value to consider the situation of student with visual impairment who is not asked to complete all work in handwriting and is, for example often permitted to record on tape. If we accept the disability of the student for e.g. who is learning disabled, behaviour disordered or intellectually disabled as real then the same philosophy could apply. There may be nearly endless variations, and the best one to use is the one that is best accepted in a given school system. Tests may be modified as to number of questions asked. Tests may be modified through simplification of the wording of questions. Tests may be given on tape and/or students may be permitted to answer on tape. Test questions may be presented orally. Combinations of 1, 2, 3 and 4 above or other similar ideas.

91 Programme adaptations and modifications may be effective only in that they teach the students that he/she can get by with less effort than other students or the selection of questions may by-pass some of the most critical skills. 4.3.5 Curricula with Functional Tasks Functional tasks for children without disability and persons with disability are required to learn now or in the future. To design a curriculum for particular students, tasks are to be selected. The curriculum for each student is organized and emphasizes the functional nature of each task. For example all three students are of ten years of age. Student one is blind and is capable of passing to the next level of academic study. His/her long term goal is to enter University study. His/her programme is mainly academic. He/she is also being taught a number of functional skills relating to general community. A few skills related to functional at home are also being taught. Student two has a moderate degree of intellectual disability. He/she has not learned many academic skills and will not likely learn many more. His/her long term goals are for sheltered employment and independence in the community and home. He/she will likely to have considerable time for recreation. There are many functional skills in the community and home that he/she needs to learn. His/her programme should focus on teaching functional and recreational skills for the community and home environment. As he/she gets a little older, the amount of emphasis in the vocational area will be increased. Student three has a locomotor disability with mild degree of intellectual disability. He/ she is not strong in academic areas of performance and will likely not achieve a high academic level. He/she is capable of learning some additional practical academic skills to assist him/her in other areas of his/her life. With suitable training he/she will likely be able to gain independent employment. His/her programme will focus on training of vocational skills. He/she will also be taught a number of functional community skills. The programmes for each of these students should be reviewed every year and the relative amount of emphasis in each area of instruction should be adjusted as required. 4.3.6 Functional curriculum Consider the existing standard curriculum used by non-disabled children,.

92 the common aspects found in the three areas are: Students needs and potentials Demands placed on him by the environment Existing standard curricula A curriculum developed thus is called 'functional curriculum'. Learning activities in a functional curriculum are chosen because they will maximize the student's independence, self direction, and enjoyment in every day school, home, community and work environment. 4.4 Adaptation, Accomodation and Modification for Pre academic Curriculum The early childhood years (0 to 6 years) are viewed by many as a critical time for the intellectual and social development of any child. Children in the age range of 0 to 3 years receive training in early learning skills while those children in the age range of 3 to 6 years preprimary education.

The Pre-Primary level programmes and early intervention programmes aim at reducing further damage to the child. The pre-school classes for children with ID emphasize content areas that are commonly referred to as readiness skills, which are prerequisites for later learning.

Pre Primary classes for these children start at an early age and the training may take as long as two or four years.

Depending on the level of disability of the child, primary education can be provided in the regular play school/nursery schools too. As the curricular content will be predominantly language, social, personal and motor skills, there is a possibility that the child with ID will be able to learn with children without disabilities. The pre-school curriculum of regular education is more conducive to inclusive practices because of the following: The content focuses on motor, language and daily living skills that is required for children with mental retardation or developmental delayed ones also. Most of the learning at this age is concrete and activity based. Worries about achieving 'high scores' is not a concern at this age and therefore the child does not face stressful demands from school and family. Children with without disabilities have an opportunity to learn from each other. There is a scope for enhancing social competency due to exposure to natural environment.

93 Non-disabled children develop positive attitudes and learn to appreciate individual differences. 4.4.1 Focus of curriculum - In a regular preschool the curriculum will focus on skills needed at pre operational stages and therefore many of our students with mild developmental delays will benefit from these adaptations & modifications at regular preschools. Readiness skills include the abilities to: Sit and attend to the teacher Discriminate auditory and visual stimuli Follow direction Develop language skills Improve gross and fine motor co-ordination Develop self-help skills Interact with peers in a group situation Suitable mobility skills Pre reading, pre writing and premath skills 4.4.2 Basic Considerations: While preparing

a training curriculum for the pre-school level, the following basic considerations may be made.

Children learn through imitating people around them. This is a first step in organizing information from the external world.

Hence encourage interaction between children and their environment.

Provide children with experiences that stimulate all sense. Multisensory approaches to teaching can facilitate assimilation and accommodations.

Assimilation refers to, use of mental schemata to comprehend new objects in the environments, in older persons it refers to tendencies to see and interpret things according to the pre-existing ideas. Accommodation on the other hand, is an adjustment of schemata to new objects, events

and ideas. Because the child has difficulty in organizing himself, the teacher must give stimulation. Children should have an opportunity to become more aware of their bodies and maintain control over their actions. Programme should be developmental in the most basic areas and should focus on the child's actual functioning level.

Knowledge of the normal sequence of cognitive development can aid the teacher in providing appropriate intervention programme.

94

Teaching strategies should be consistent, structured and controlled. Set goals and plan activities with clear objectives in mind.

Action oriented activities facilitate attainment of the goal Do not waste time to teach the activities that do not have a functional value in the immediate environment and later stages

in life. 4.4.3 Major focus at preprimary level will include Self - Body parts, name, gender, family members, daily living skills Common objects - clothing, food, furniture, toys, dishes, utensils, plants, animals, holidays Action Words - sit, stand, walk, run, clap, jump, hop, top, stop, go, drink. Concept - Shapes, size, color, sound, taste, smell, texture, position, weight, beauty, same and different, laterality, safety. Preacademics - readiness skills for reading and writing and math.

Pre-reading may include activities such as seeing picture books, holding it properly, turning pages and enjoying seeing and naming pictures and talking about it. Pre writing may include activities such as scribbling, colouring pictures, tracing pictures and so on. Pre math skills include concepts such as far-near, up-down, heavy-light, long-short, more-less, full-empty and so on. All of these pre academic skills lead to preparing the child for learning academics later. 4.5 Adaptation, Accomodation and Modification for Academic Curriculum - Academic activities depend to a great degree on the quality and extent of the pre-school programming in individual child

has had. The curriculum mainly consists of components that may be taught independently or together and to relate to long-range goals for academic and social education. It is wise to try using the regular school content simplified and taught so that the concept is understood. If the child tends to fail as the content becomes more abstract, functional curriculum can be considered.

Functional academics are stressed where the child is unable to cope with the regular education curriculum. 4.5.1

Functional Academics - The functional academic refer to the literacy and numeracy skills required to teach the

95 children with ID for leading independent lives in the society. It includes reading, writing and arithmetic. 4.5.2 Functional Reading Functional reading is defined as a student's actions or responses resulting from reading the printed word.

Primary goal is the development of their ability to read for protection- sign boards, labels, directions and so on (concept of survival)

The second goal is reading for information and instruction- newspaper, telephone book, job application and so on. The third goal is reading for pleasure-magazines, comics, story books.

Whole word approach is a widely used method in teaching functional reading. Through the whole word approach, the students learn to recognize and read words and later receive decoding instructions (to spell).

A variety of strategies have been used in teaching sight word vocabulary. Recent attention has been focused on the imagery level of the word to be learnt.

High imagery words are usually concrete and include nouns such as ball, mango, fan and house. Low imagery words include abstract terms such as beautiful, good and have. In some instances, high imagery can be provided for low imagery words by using the word in context. For example, consider the word "sour" "I ate mango. It is sour", becomes more concrete and students can remember better. Pairing of words with concrete objects and / or pictures will facilitate development of a high imagery level in the students. Here, the concrete word mango helps in learning the abstract word 'sour'.

Keeping inclusion in mind, try to follow the primary level text books, simplify the concepts for children with mental retardation and help them read using whole word approach initially and then the parts of the word (spelling). Reading and writing should be planned together to allow for multisensory input. 4.5.3

Functional Writing One of the important modes of communication is written expression. Writing demands eye hand coordination, motor coordination, sense of direction and recognition of symbols (pictures/letters/numbers/punctuations and so on). Some writing tasks demand horizontal writing (left to write as in writing words)

and some demand vertical writing as in arithmetic (addition, subtraction) and some demand a combination of both as in statement sums.

96 Teaching writing involves four stages they are: 1.

Tracing 2. Joint dots (if needed) 3. Copying 4.

Fill in the blanks 5. Writing from memory (including learning spelling) To write sight words, students have to go through six steps using auditory, visual, tactile and kinesthetic inputs. 4.5.4

Functional Arithmetic We are in daily contact situations which require the use of number skills.

For example, when we buy half a dozen bananas from the fruit vendor we glance at the bunch to check whether it contains six bananas or not. We use number skills in various settings such as at home, in community and at work place, for example,

how many plates to place on the table, which bus number to take to reach work place, how much is the bus fare, how long it takes to reach office and so on.

Before beginning with numbers, make sure, the child is aware of pre-math concepts such as more-less, far-near, heavy-light, tall-short-long, left-right

and so on. The following are the points to be considered while planning and teaching arithmetic skills. The content should be arranged in a sequential order for which the task analytic approach is applied. Concrete materials should be used while teaching to provide meaning for the concepts. The selection of materials should be such that they can be used meaningfully both inside and outside the school environment. The programme should be structured in such a way that there is a gradual transition in teaching concepts moving from concrete to semi-concrete and abstract levels.

Instruction must be practical and functional with special emphasis given to social and vocational orientation.

97 Sufficient practice should be given to deal with the concepts in variety of ways to ensure understanding. Additional opportunities should be provided to generalize the skill to a variety of experiences to note similarities and to establish associations and relations among these experiences. Practical experiences and situations should be provided for the application of numerical skills. However, care should be taken in planning the application of number skills to the real life experiences that they should have relevance to the world in terms of the individual child's needs. A programme must be flexible to meet the individual needs of students.

A functional mathematics curriculum should include, time, money, measurements (mass, volume, weight, distance) which are necessary for daily living activities. The content must be graded from easy to difficult distributed from preprimary to prevocational levels.

One of the successful environments for inclusion of children with ID is the class of co- curricular activities. There is scope for natural and spontaneous integration of children with and without disabilities. If well planned, it enhances positive self concept, releases tension and anxiety, develops social skills, sharpens creativity, leads to physical fitness and sense of well being, inculcates discipline and helps the student to learn to use his leisure time well. When a teacher plans for co-curricular activities, she has to keep the above goals in mind and plan carefully.

A competent teacher will, Schedule co-curricular activities with due importance; Avoid combining more than one class to make large groups (unless it is a whole school event)

which would reduce individual attention to children with special needs; Avoid using co-curricular class periods to use children to run errands - moving furniture, clean the class and so on; Avoid deprivation of co-curricular activity class as a punishment; Avoid using the co-curricular time for other curricular activities; Develop a well planned IEP with specific goals and objectives for co-curricular activities including evaluation procedures;

98 Equip the class well with necessary resource material; Update herself with latest trends and developments in co-curricular activities; Use technology wherever appropriate; Be innovative in activities as well as in individual adaptations for the students with specific needs. 4.6 Adaptation, Accommodation and Modification for Co- Curriculum:

Co-curriculum is a structured activity which supports for the curriculum in practical way in education programmes. Any activity organized systematically apart from the syllabi of subjects of classroom is considered as co-curriculum. There is no separate co-curriculum for children with special needs. However, all co-curricular activities cannot be carried out by the children with disabilities due to their limitations, so they need adaptations in their approach, method, and materials. The children with Intellectual disabilities select co-curricular activities based on their abilities, interests, motivation and encouragement. The following are certain aspects we have to keep in mind to select co-curricular activities. 4.6.1 Assess abilities and needs Some co-curricular activities are purely for fun. Others require a certain level of ability. Making a good match between the activity and the child's unique abilities, interests, and needs is the first step. 4.6.2 Interaction with the Child Co-curricular activities should be challenging. They should provide relaxation, satisfaction, and in most cases - socialization. Above all they should be enjoyable. Talk to the child about the kinds of things he/she likes to do. 4.6.3 Choose activities Our society offers lots of choices for free time. The child will not be able to sign up for everything, so you will need to help him/her to select. Beyond interests and special needs you will need to consider some other factors when choosing co-curricular activities. a) Age Consideration: A young child needs some unplanned time to explore the

99 world around him/her. As the child gets older, he/she may be ready to participate in some group activities. Schedules are helpful for children with learning disabilities or autism and those with cognitive delays. Young children need some time to figure out what to do next. b) Realistic Commitments: Children with intellectual disabilities especially need to focus on a reasonable amount of activity. Too many parts to the schedule or too many new situations (and rules) can be overwhelming for them. c) Balance with Schoolwork: Even with modifications and accommodations, schoolwork will take longer time to complete than it does for his/her siblings. Take schoolwork into consideration when signing up for co-curricular activities. 4.6.4 Consider Interests Your child may have ability in areas that are not of high interest to him/her. Co-curricular activities are sometimes recreational, pass time and they should be enjoyable. They are not compulsory insisted schoolwork or jobs. Talk to the child to know about his/her interests. For example : Athletics Art and Music Community service 4.6.5 Community Groups Some activities are not offered through schools. If the child is interested in learning how to train the family dog, for example, he/she will need to look for a community group that focus on animal care. 4.6.6 Groups with Special Needs Grouping is formed based on the conditions of disabilities. For example, if a child in a wheelchair wants to bowl a ball, he/she may sign up for bowling leagues that will use ramps and have volunteers to assist the bowlers. A child who is blind might enjoy outings with sighted peers. In the inclusive schooling, the child with disabilities is fixed with the non-disabled children for all activities including co-curricular activities.

100 Adaptations are to be given to the children with disabilities wherever essential which will help them to have co-curricular activities as that of non-disabled children. 4.6.7 Family involvement The family members are to be oriented about the abilities of the child to participate in co-curricular activities. Naturally the members of the family may have hesitation to provide co-curricular activities because of fear about the child's safety and sometimes not knowing of the child's needs and required adaptations. In this regard, the teacher has to give clear idea about the requirement of the child for co-curricular activities. 4.6.8 Co-curricular activities for children with intellectual disability Special Olympics offers year-round training and competition in 25 Olympic type sports to children and adults with intellectual disability. Participation is open to anyone from ages eight and

above up, and programs are designed to serve all ability levels. Official Summer Sports Aquatics Athletics Basketball Bowling Cycling Equestrian Sports Football (Soccer) Golf Gymnastics (Artistic and Rhythmic)

Power lifting Roller Skating Softball Tennis Volleyball

101 Official Winter Sports Alpine Skiing Cross Country Skilling Figure Skating Floor Hockey Speed Skating National Popular Sports Cricket Football Volleyball Kabadi Badminton Table Tennis Team Handball. 4.7 Adaptation, Accommodation and Modification for school/ subjects A teacher of children with Intellectual Disability has to carefully consider the three types of adaptations for her students, based on their ability level and the type of educational placement (special school, special class in regular school, resource room, home based education). As Janney & Snell (2000) note, knowing whether the student's objective in a particular subject will be supplemented, simplified or altered will help to clarify the relationship between his learning objectives and that of his classmates.

It has to be kept in mind that different subject areas may need different adaptations. For example, for a student, science may be simplified; language may be supplemented while math may need to be altered.

The student's interest and age may also play a role in selection of the type of adaptation.

High interest subject may need fewer adaptations. It may also be that a teacher may use one type of adaptation in curriculum for a student at a particular point of time and may use another type of adaptation at other times. For 102 instance, for a student in math, curricular content of geometry may be simplified while basic four computation skills may be supplemented while algebra may be altered. Teacher should keep in mind that within the context of class room, simplified and supplementary curriculum meet the needs of special education. Alternative curriculum are used in special schools or special class in regular schools. 4.7.1

Simplified Curriculum Simplified curriculum includes fewer concepts and skills rather than the entire scope of the general curriculum. Example: Science: Structure and functions of parts of the eye The text books have detailed description of parts of the eye with difficult terminology and how the eye functions (iris, pupil, cornea, lens, aqueous humor, vitreous humor, optic nerve).

A child with ID can just be taught major parts and functions. The parts that are visible so he comprehends (eye lid, pupil, iris, lens)

and focus on care of eyes, signs of problem with eyes, care of eye glasses and such other information which is more functional and simplified yet taken from regular educational curriculum. 4.7.2 Supplementary curriculum Supplementary curriculum includes basic skills of reading, writing and math and also additional social skills, study skills and learning strategies. This helps children in organizing themselves, improve memory and learning ability. This type of curriculum is most useful to children with learning disabilities and those with emotional/behavior problems. Example: Student attends regular class but performs poorly in exams. In such cases, supplementary classes are provided in test taking, organizing time, noting main points etc. 4.7.3 Alternative Curriculum An alternative curriculum emphasizes skills needed to participate in activities in the community living domain of the curriculum. An alternative curriculum therefore, can be a functional, community referenced curriculum, determined by assessing the student and his environment. Functional academics forms part of the community referenced curriculum. Depending on the severity level of disability, emphasis can be on personal,

103 social, communication skills. Opportunity for partial participation in school activities is recommended for severely disabled children.

For example, if the class curriculum demands gardening activity, a severely disabled child may perhaps participate by holding the hose pipe for watering plant, with the support of a peer. He may receive his individualized interaction which may have minimum common content with his age appropriate regular curriculum. It is an alternative curriculum with the common objective of leading towards independent living. 4.7.4

Multilevel Curriculum Another commonly used form of curricular adaptation is, 'multilevel curriculum'. This involves having objectives at varying levels of difficulty for different students in the same class. Thus in mathematics class one student may do two digit addition with carry over, another without carry over and yet another may be doing single digit addition, all doing curricular content - addition. This is commonly seen in most of the special schools for children with intellectual disability. 4.7.5 Activity Based Curriculum When the students belong to different levels, planning and implementing instructions in difficult. Activity based curriculum is based suited for children with mental retardation as it provides experience based learning. Because of the multi-sensorial input and the experience of carrying out the task, the students are likely to retain the learnt information better. For example, teaching freezing point, boiling point, evaporation and such concepts with black board and text books are too difficult for a child with mental retardation to understand. The same concepts included in their curriculum with the teaching method focusing on demonstration using boiling in a kettle and freezing using a refrigerator - all done by the students under supervision and guidance will be better understood. Demonstration of use of thermometer showing boiling and freezing points on it will be better comprehended by them. Though time consuming and requires a lot of efforts, it is one of the best way to plan and teach students with mental retardation. A good curriculum has inbuilt evaluation procedures. As evaluation provides information on effects and effectiveness of the training it is very essential to structure evaluation carefully and objectively. If the student attends regular education, the examination systems need modification focusing on testing student's learning. A few examples are, simplifying directions in a test paper so that a child with mental retardation understands, providing example if the instruction is difficult to comprehend or allowing to write one

104 word/few word answers if it conveys the correct response. Provide alternatives to exams such as projects, reports, action oriented content and so on. The student may be at different levels Bloom's taxonomy of cognitive domain(1956). This includes knowledge, comprehension, application, analysis, synthesis, and evaluation. See box for an example. Find out at what stage the student is in and suitably plan the instruction for each curricular content area. Example of Bloom's taxonomy of cognitive domain Knowledge Define, list name 1. Name the capital of India 2. How many states are there in India? Comprehension Explain & Summaries 1. What is a Union Territory? in your own words 2. What is a peninsula? Application Dramatize, practice, Make a model of India and apply, compute show the mountains and rivers Analysis Interpret, categorizes, 1. What are similarities and Compare, group, order differences in the festivals celebrated in various parts of India Synthesis Create, formulate, Compose song/write 5 develop, improve, lines to express 'nifty in rearrange diversity' in India. Evaluation Judge, criticize, assess, Report the importance of infer, conclude National language in India. A Child with mental retardation may be at different levels of this taxonomy, identify the levels and suitably develop his evaluation plan. To be successful; Identify strengths and needs Specify instructional objectives Plan curriculum and sequence items to be taught Select activities for each skill domain/subject. Teach in variety of environment Provide opportunities to practice Ensure mastery.

105 4.8 Let us sum up: The educational provision for students with special needs in India in the recent two and half decades is being focused on regular setting where they get equal educational opportunity as other non-disabilities peers which we call as integration, mainstreaming or inclusion.

Curriculum adaptation tends to be significant at all grade level, but teachers have to develop their own style of presentation or teaching strategy, which may be related to how they teach or the availability of instructional materials in schools. Presentations may include combinations of lectures, assignments, or a host of other teaching / learning approaches. Curriculum decisions are founded on the beliefs and values regarding the purpose of education and the benefits of its outcome. Every curriculum aims at realizing the fullest potentials of students and helping them become productive and contributing members of the society. When we look at children with disabilities, their abilities and needs are varied, demanding adaptation in curriculum content and transaction without compromising on the objectives and learning outcomes. The common focus in schools is to develop competencies in Leading independent lives Developing and maintaining positive relationship with family and community Carrying out day to day activities in an acceptable manner and Being a good citizen Adaptations in instructional strategies are needed, and given much priority, so as to make it possible for the student to achieve goals that are determined by the teacher is more important. Basic to any training programme for these children with Intellectual Disability, is the knowledge and skill regarding the individualize education programme. Individualized training programme : The individualized training programme should be based on the assessment with reference to the academics. ADL., social skills, personal skills, vocational skills and community skills and plan for training is developed with objectives, strengths, and weaknesses.

106 Skill Development: The specific skills to be developed among children with Intellectual Disability based on the extent of Intelligent Quotient (IQ). The organization of teaching materials is important for all students including children with disabilities. But

students with disabilities may need materials that are different from those required by normal students. Most of the special teachers prepare learning activities to satisfy the educational needs of children with disabilities so that maximum educational benefit can be derived. The teacher

has to use the combination of instructional strategies to suit the educational needs of learners. Programme adaptations and modifications may be effective only in that they teach the students that he/she can get by with less effort than other students or the selection of questions may by-pass some of the most critical skills Functional tasks for children without disability and persons with disability are required to learn now or in the future. To design a curriculum for particular students, tasks are to be selected. The early childhood years (0 to 6 years) are viewed by many as a critical time for the intellectual and social development of any

child. The pre-school classes for children with ID emphasize content areas that are commonly referred to as readiness skills, which are prerequisites for later learning.

In a regular preschool the curriculum will focus on skills needed at pre operational stages and therefore many of our students with mild developmental delays will benefit from these adaptations & modifications at regular preschools.

Academic activities depend to a great degree on the quality and extent of the pre- school programming in individual child

has had. The curriculum mainly consists of components that may be taught independently or together and to relate to long- range goals for academic and social education.

To cope with the regular education curriculum. Functional Academics - The functional academic refer to the literacy and numeracy skills required to teach the children with ID for leading independent lives in the society. It includes reading, writing and arithmetic.

107

Co-curriculum is a structured activity which supports for the curriculum in practical way in education programmes.

Some co-curricular activities are purely for fun. Others require a certain level of ability. Making a good match between the activity and the child's unique abilities, interests, and needs is the first step. Co-curricular activities should be challenging. They should provide relaxation, satisfaction, and in most cases - socialization.

A teacher of children with Intellectual Disability has to carefully consider the three types of adaptations for her students, based on their ability level and the type of educational placement (

special school, special class in regular school, resource room, home based education). Teacher should keep in mind that within the context of class room, simplified and supplementary curriculum meet the needs of special education in general setting while alternative curriculum are used in special schools or special class in regular schools. 4.9 Check your progress: What is Curriculum adaptation? Adaptations in evaluation procedures?

..... What is Functional curriculum? What are the Major focus at preprimary level? Short Note: Co-Curriculum, Simplified curriculum, Supplementary curriculum, Alternative Curriculum, Multilevel Curriculum

Drama Therapy 5.7.4 Dance and Movement Therapy 5.7.5 Sports Activities for Children with Special Needs 5.8 Let us Sum Up 5.9 Check your Progress 5.10 Reference 5.1 Introduction Treatment of developmental disabilities can come in a variety of different forms. The best treatment regimens are the result of an individualized treatment plan formed by a team of health care multidisciplinary professionals. The plan will be based on the severity of the disability and should involve patients, families, teachers, and caregivers in all phases of planning, decision making, and treatment. The individualized treatment plan will take into consideration both the immediate needs of the patient, and the long term prognosis for development.

165 Occupational therapy, or OT for short, is a treatment therapy that helps people achieves independence in all facets of their lives. If a child has physical disabilities or developmental delays, occupational therapy can improve their cognitive (thinking), physical and major skills as well as address psychological, social, and environmental factors that impact the child's functioning. Physical therapy (PT), or sometimes called physiotherapy, focuses on improving gross and fine motor skills, balance and coordination, and

strength and endurance. The child may be evaluated by a physical therapist to assess muscle and joint function, mobility, strength and endurance, oral motor skills such as feeding and talking, posture and balance, even the status of the heart and lungs. Speech therapy is a clinical program aimed at improving speech and language skills and oral motor abilities. This means talking, using sign language, or using a communication aid. Children who are able to talk may work on making their speech clearer, or on building their language skills by learning new words, learning to speak in sentences, or improving their listening skills. Dance and creative movement provide physical challenges in a structured, supportive environment for sensory integration. The intimate connection with music often makes dance feel less like exercise or physical therapy and more like leisure. Dance/Movement Therapy (DMT) has been used in the United States since World War II. Marian Chace, a dancer, choreographer, and teacher of modern dance in Washington D.C. during the 1930s and 1940s, first developed the mind-body connection as a form of therapy for her dance students. She "questioned why pupils who had no intention of being professional came to take dance classes" and started gearing her classes toward the needs and interests of recreational dancers. In 1942, she was asked to work with returning soldiers from World War II at St. Elizabeth's Hospital in Washington D.C. Dance/movement therapy was seen as promising because it could so easily be a group treatment. Chace developed her methods working with institutionalized, often schizophrenic and psychotic, individuals. Music therapy enhances one's quality of life, involving relationships between a qualified music therapist and individual; between one individual and another; between the individual and his/her family; and between the music and the participants. These relationships are structured and adapted through the elements of music to create a positive environment and set the occasion for successful growth.

166 Music Therapy is a well-established, research-based profession in which music is used to accomplish therapeutic and educational goals. Recreational therapy is based on the idea of increasing a person's independence and ability to function through participation in creative arts, dance, sports, adventure programs and puzzles or logic games. It is a holistic approach to wellness. According to the American Therapeutic Recreation Association, recreational therapy "aims to improve an individual's functioning and keep them as active, healthy and independent as possible in their chosen life pursuits." In most cases, these goals are accomplished by combining a person's speech, fine motor or gross motor goals with community involvement, while engaging in the person's preferred interests. 5.2

Objectives After going through this unit you will be able to ?

Define

the

different therapies like occupational, physio, speech, yoga and play, music, dance and movement. ? Discuss the aims and objectives of the different therapies. ? Narrate the scope and modalities of the therapies. ? Describe the intervention procedures of the therapies. 5.3 Occupational Therapy: Definition, Objectives, Scope, Modalities And Intervention. 5.3.1

Definition of Occupational Therapy Occupational therapy is a method of treatment for which the primary area of concern is the patient's ability to perform functions required in day to day life. This method of treatment is also concerned with the social, psychological and cognitive development of the patient. In the early years, occupational therapy was regarded as a means to keep long term convalescent patients occupied. It derived the name "Occupational therapy" owing to this. Its contribution was limited to the field of chronic illness - mental illness, tuberculosis, leprosy etc.

Occupational therapy is a client-centred health profession concerned with

167 promoting health and well-being through occupation. The primary goal of occupational therapy is to enable people to participate in the activities of everyday life. Occupational therapists achieve this outcome by working with people and communities to enhance their ability to engage in the occupations they want to, need to, or are expected to do, or by modifying the occupation or the environment to better support their occupational engagement. (WFOT 2012) "

Occupational therapy is the art and science of directing man's participation in selected tasks to restore, reinforce and enhance the performance, facilitate learning of those skills and functions essential for adaptation and productivity, to diminish or correct pathology and to promote and maintain health." (Council of Standards, American Occupational Therapy Association, 1972) 5.3.2 Aims of Occupational Therapy A person with intellectual disability is observed to have dysfunction in almost all performance components. The specific aims of occupational therapy for persons with intellectual disability are as follows. (a) To facilitate the development of performance components of the patients. (b) To enhance independence of the patients. (c) To provide sensory stimulation. (d) To improve hand functions. (e) To enhance gross motor functions. (f) To facilitate development of perceptual motor functions. (g) To reinforce social development. (h) To enhance independence skills. (i) To provide vocational training. (j) To correct mal adaptive behaviour. (k) To provide extrinsic adaptations.

168 5.3.3 Objectives of Occupational Therapy Occupational Therapists work with children who have difficulties with the practical and social skills necessary for their everyday life. An Occupational Therapist will aim to enable the child to be as physically, psychologically and socially independent as possible. Occupational Therapists work in close partnership with the child and their family, schools and other healthcare professionals. Together they have a shared responsibility for meeting the child's needs. In schools, for example, they evaluate the child's abilities, recommend and provide therapy, modify classroom equipment, and help the child participate as fully as possible in school programs and activities. A therapist may work with the child individually, lead small groups in the classroom, consult with a teacher to improve the functioning skills of the child etc. Occupational therapy is provided when there is a disruption in function in one or more of the following the areas: Gross Motor Skills: Movement of the large muscles in the arms, and legs. Abilities like rolling, crawling, walking, running, jumping, hopping, skipping etc. Fine Motor Skills: Movement and dexterity of the small muscles in the hands and fingers. Abilities like in-hand manipulation, reaching, carrying, shifting small objects etc. Cognitive Perceptual Skills: Abilities like attention, concentration, memory, comprehending information, thinking, reasoning, problem solving, understanding concept of shape, size and colors etc. Sensory Integration: ability to take in, sort out, and respond to the input received from the world. Sensory processing abilities like vestibular, proprioceptive, tactile, visual, auditory, gustatory and olfactory skills. Visual Motor Skills: A child's movement based on the perception of visual information. Abilities like copying. Motor Planning Skills: Ability to plan, implement, and sequence motor tasks. Oral Motor Skills: Movement of muscles in the mouth, lips, tongue, and jaw, including sucking, biting, chewing, blowing and licking. Play Skills: To develop age appropriate, purposeful play skills Socio-emotional Skills: Ability to interact with peers and others.

169 Activities of daily living: Self-care skills like daily dressing, feeding, grooming and toilet tasks. Also environment manipulation like handling switches, door knobs, phones, TV remote etc. Occupational therapists in schools collaborate with teachers, special educators, other school personnel, and parents to develop and implement individual or group programs, provide counselling, and support classroom activities. Occupational therapists design and develop equipment or techniques for improving existing mode of functioning. 5.3.4 Scope of Occupational Therapy Occupational Therapists work with parents/care givers and others to assess if a child has difficulties with practical and social skills. Occupational Therapists assess the physical, psychological and social functions of the individual identify areas of dysfunction and involves the individual in a structured programme of activity to overcome disability. Following assessment, the Occupational Therapist will design and implement programs with appropriate strategies in order to enable the child to maximize his/her potential. Occupational Therapists provide services to individuals often in conjunction with physicians, social workers, psychologists, and other therapists. Occupational therapists use qualitative and quantitative assessment methods, including standardized tests, as well as devices, to analyze and diagnose the nature and extent of dysfunction. Occupational therapists develop an individualized plan of care, tailored to each patient's needs. 5.3.5 Modalities of Occupational Therapy Occupational Therapy is a form of treatment which directs the patients to practice and master human activities. Thus human activity is indeed the foremost modality of occupational therapy. The modalities of occupational therapy

are as 1. Human Activity. 2. Extrinsic adaptation: Extrinsic adaptation is a adaptation in the physical, natural or non human environment of the person. Here adaptation refers to the structural adjustment or change in factors in the environment.

170 3. Splints and pressure garments. 4. Therapist. 5. Environment 6. Teaching/ Learning Process. 5.3.6 The Intervention Process Occupational therapy intervention for people with intellectual disability is an on-going process that is both gradual and dynamic. Treatment is provided throughout the life cycle in accordance with the client's changing needs, desires and preferences in all areas of occupation. The intervention often requires repeated drills and practice to achieve internalization and learning, and performance in a variety of contexts to enable generalization. As is the case with respect to assessment, the intervention is preferably carried out in the client's various daily environments. This enables and encourages the client's participation in the many contexts of his/her life. Occupational therapy interventions for people with intellectual disabilities are specifically adapted to the client with respect to the degree and type of support needed as well as the context. Interventions may include direct treatment as well as environmental adaptations, guidance, monitoring and counseling (including of the family, the educational staff, the clinical staff, employers and others).
Examples of Occupational Therapy Intervention: Activities of daily living: including activities directed to the person's care of his/her hody needs (ADL) such as personal hygiene, eating, dressing, and instrumental activities of daily life (IADL) such as preparing a meal or managing finances. This area represents a central focus of i rtervention in occupational therapy for this population. For example, with respect to activities related to eating, the intervention can range from adapting the feeding environment, choosing preferred food or bringing the food to one's mouth, to teaching more advanced skills such as organizing shopping, and meal preparation. Learning/Studies: These are activities necessary to be a student and to participate in a learning environment, including academic and non-academic activities. Intervention in this area covers a variety of educational settings such as day care centers for very young children, kindergartens and special education schools (ages 3-21 years), regular school settings and professional training facilities. The intervention is varied and may focus on
171 gaining basic learning-skills, such as understanding cause and effect processes and object permanence, or on more complicated skills, such as preparation for learning and writing, organization in time, in space and with accessories, adaptation to different learning environments, the use of information technologies and computers and gaining learning strategies. In addition, the intervention can include adapting various learning environments. Work: These are productive activities, whether for remuneration or not, that include preparing for work, producing a product and providing services. Intervention in this area covers a variety of work settings including: special educational settings in which students receive training to enter the work force, youth rehabilitation centers, adult sheltered-work facilities, an array of protected supportive community work systems, and placement-services for gaining open market positions. Intervention varies and may include basic work skills training (behavior norms, work routines), developing and practicing basic cognitive abilities, practicing motor skills, exposure to varied work opportunities, support and advice for developing areas of interest, identifying abilities and choosing suitable occupations, analyzing occupations and adapting them as needed, as well as supporting and assisting placement in various work sights in the community. Play: These are activities that are generally internally motivated and provide pleasure, entertainment and learning. Play-intervention, as an occupational therapy goal in this population, is directed towards the most basic experiencing of playas a source of pleasure, as well as providing the client with an opportunity to participate in play activities. The intervention includes drills in basic skills such as the use of equipment, recognizing rules and agreed-upon behavior patterns, or choosing suitable play activities. In addition, play represents a treatment method for learning and practicing a variety of social, motor and functional skills. Leisure: These are non-obligatory activities that are internally motivated and are performed at times that are not devoted to work, studies, self-care or sleep. Research reveals that people within this population have a relatively large amount of time to devote to leisure, whereas their participation in leisure activities is minimal (Buttimer & Teirney, 2005). Therefore, coping with leisure within this population is a central topic. Intervention in this area may focus on exposure to varied leisure opportunities, identification and choice of areas of interest, planning leisure time and participation in activities that lead to a perception of capability, pleasure, control and satisfaction.

172 Social participation: These are activities related to agreed-upon behavior patterns expected of an individual within a given social system (e.g. community, family or with friends). The intervention within occupational therapy encourages the person to gain skills in the various areas or occupation and thus supports and strengthens social participation. For this population, an emphasis is placed upon understanding acceptable social norms and as well as learning and practicing activities that lead to satisfactory social interactions. Accessibility and Environmental Modification: Occupational therapy practice relates to the person, the occupation and the environment. The occupational therapist's broad knowledge base in the areas of function and limitation enables him/her to identify, through performance analysis in the different areas of occupation, environments and/or tasks that should be modified. The various limitations that characterize the population of people with intellectual disabilities require both general and client-specific environmental modifications to ensure accessibility. The characteristic difficulty in problem-solving, initiative and coping with unfamiliar situations, amplifies the need for accessibility modifications for this population. These accessibility modifications include changes in the environment (as in widening passageways, modifying playgrounds or adding symbol signs), in the equipment (such as adapting seating systems or adapting feeding aids), or in the task (such as changing the complexity of instructions or dividing a task into sub-stages). Assistive technology is one of the methods used to adapt the environment and includes modifications of hardware; software and various combinations thereof (such as a virtual keyboard, a touch screen, a motorized wheelchair, switch systems, computer programs and internet sites, adapted content amount, or voice output devices). Thus, for example, a switch can be modified to be activated through the person's head or hand. Other modifications of the switch may include size, colour, texture, or sensitivity (such as speed or pressure response). Assistive technology promotes a variety of functions related to the individual, the occupation and the environment. In addition, it allows for the modification of an individual's environment in the manner in which his/her requires, by relating to his personal abilities, wants, areas of interest and specific limitations and difficulties. Environmental modification is likely to significantly improve a person's ability to participate in all areas of occupation, his or her level of independence and the degree of supports required.

173 In summary, the occupational therapist, as part of a therapeutic, rehabilitative and educational profession plays a central role within the support system available to people with intellectual and developmental disabilities, throughout the life cycle. As such, occupational therapists hold key positions as leaders in this area. Working with people with intellectual and developmental disabilities requires consideration of function, independence and participation in the various areas of occupation, which enables the occupational therapist to utilize all the areas of knowledge and expertise included in the practice of occupational therapy.

5.4 Physiotherapy: Definition, Objective, Scope, Modalities and Intervention 5.4.1 Definition of Physiotherapy It is also called physical therapy. The treatment of physical dysfunction or injury by the use of therapeutic exercise and the application of physical modalities (like heat, light, cold, current, water, sound waves).

Assistive devices are also used as a part of the treatment programme. They are intended to restore or facilitate normal function or development.

5.4.2 Aims and Objectives of Physiotherapy

Physiotherapy in the field of mental retardation is aimed at improving overall motor functions of the child to the maximum extent possible,

so as to make the child independent in walking and carrying out activities of daily living. If it is not possible for the person to walk, and carry out activities independently, then aids and appliances are trained given to the person to use it. (A)

Objectives of physiotherapy in general

1. Reduces or relieves pain, muscle spasm, tenderness of muscles.
2. It helps to reduce or relieve swelling.
3. It helps to reduce or relieve inflammation (means the response of the body in the form of pain, swelling, muscle spasm and tenderness of the muscles etc. in the presence of any foreign body).
4. To improve ventilation of lungs, by giving, deep breathing exercises and postural drainage.

174 5. To encourage correct weight bearing and weight transference on both sides of the body. 6. Re-education of affected or paralysed muscles. 7. It is effective in healing of infected wounds. 8. It helps to check the abnormal growth of bone (bony spurs). 9. Breaking up of adhesion formation (gluing of joint structures by synovial fluid). 10. To keep the person physically fit. 11. To teach relaxation. 12. Stimulation of sensory and motor nerves if sensations are reduced or lost. 13. Post fracture and dislocation, management. (B) Objectives of physiotherapy in relation to Intellectual Disability 1. To facilitate the development of child gross motor and fine motor. 2. To prevent or correct contractures and deformities. 3. Prevent or correct wasting and atrophy of muscle. 4. To normalize muscle tone. 5. To maintain or improve the muscle power. 6. To maintain and improve the joint range of movement. 7. To emphasize the importance of handling and positioning the child. 8. To make the child independent in walking and activities of daily living. 9. Provide aids and appliances and to train the person and parents how to use assistive devices. 10. To improve posture, gait, balance coordination. 11. Inhibition of abnormal reflex activity, abnormal patterns of movement and abnormal muscle tone and facilitation of normal in place of abnormal. 12. To keep the children physically fit. 5.4.3 Scope of Physiotherapy Physiotherapy has scope in treating a wide range of conditions. It play an important

175 role in all the branches of medical sciences, especially Orthopaedics, Paediatrics, Neurology, Cardio thoracic, Surgery, Sport Medicine etc. In set ups like leprosy, paraplegic and poliomyelitis after plastic surgery, burns clinics, spinal cord injury centres and in assistive devices manufacturing units etc. Physiotherapy has three major functions in the management of children with intellectual disability. 1. To facilitate motor development 2. To prevent and correct contractures and deformities. 4. To make the child as independent as possible and functional (locomotor function and activities of daily living). 5.4.4 Modalities of Physiotherapy 1. Hydrotherapy: Hydrotherapy, or water therapy, is the use of water (hot, cold, steam, or ice) to relieve discomfort and promote physical well-being. 2. Electrotherapy: Electrotherapy is the use of electrical energy as a medical treatment. 3. Exercise Therapy: Exercise Therapy is a regimen or plan of physical activities designed and prescribed for specific therapeutic goals. 4. Massage or Manipulation 5. Gait: Gait training is a type of physical therapy. It can help improve your ability to stand and walk. 5.4.5. Intervention of Physiotherapy Role of Physiotherapist in the field of Intellectual Disability ? Diagnostician: Here the physiotherapists assess the client and order for the necessary investigation, on the basis of this therapist arises at diagnosis. According to the diagnosis therapy will be planned. ? Interventionist: Therapist plays a role as interventionist in setting intervention goals, planning and implementation of therapy programme, giving follow - up and

176 regular evaluation of the client, modifying programme as per the clients need. ? Team member: Therapist treated as a team member as the team member in multidisciplinary approach, this is the most commonly seen approach in field of mental retardation. In Trans disciplinary approach therapist plays a role as a team member by gathering information and helps in planning intervention along with other experts of the team. In certain condition therapist become a case manager and given input. ? Providing Information and guidance: As the parents need information guidance regarding the condition of the child and therapy, the therapist gives proper information to parents and also to other professional whenever needed. ? Counsellor: Physiotherapist plays a counsellor role in the field of mental retardation. Parent counselling is in important aspect, which should be included in intervention programme. The parents of the clients may not be aware of the condition of child and the facilities available for their child. They will come to you in a state of confusion and anxiety to know what happening with their child. Before as part of planning and intervention programme therapist should give proper information to the parents regarding the following things: ? Condition of the child. ? Child's needs and abilities. ? How the therapy is going to help the child in improving his functional abilities. ? Proper instructions given to the parents. ? Training is given to the parents how to give therapy at home. ? What are the facilities and services available for the persons with intellectual disability. ? Trainer: Therapist plays a role of trainer, as the therapist will train the parents how to give therapy at home and conducts classes and workshops for parents and other professional, to make them aware of disability and affects of intervention on the clients. ? Researcher: Research is an important aspect in the field of intellectual disability. Therapist also plays a role as a researcher by doing research on different aspects

177 and population study. To innovate new techniques and equipment for making the intervention better and to get better out come results. ? Leader: Therapist plays a role of leader of the team voicing on behalf of the client and by giving guidelines to the former self-help groups by the parents. ? As an administrative officer: Therapist plays a role of administrative officer by heading and organization and establishing a institution or center to serve the people better. ? Provider of referral: Therapist will give referrals to the concern professionals to obtain information of the clients and to related services outside the institute for investigations or for expert opinion.

5.5 Speech Therapy: Definition, Objectives, Scope, Types of Speech, Hearing and Language Disorders and Intervention

5.5.1 Definition of Speech and Language Therapy: Speech and language therapy provides treatment, support and care for children and adults who have difficulties with communication, or with eating, drinking and swallowing. Speech and language therapists (SL Ts) are allied health professionals. They work with parents, carers and other professionals, such as teachers, occupational therapists and doctors.

5.5.2 Objectives of Speech Therapy A speech pathologist's narrow, well-defined objectives work toward achieving broad therapeutic goals. This professional develops an individualized treatment plan for each patient, which often includes time-based objectives. For example, his objectives may include helping a patient correctly say several new sounds by the end of a quarter, marking period or year. Other objectives can include helping a patient to understand and to explain a speaker's gestures, demonstrate newly learned conversation strategies, explain the perception of body language, speak for a period of time without stuttering and improve reading comprehension to a specific level. A speech language pathologist sets broad but specific goals for each of his patients. Specific goals can include helping patients develop clearer speech, learn to use alternate

178 methods of communication, develop better reading and writing skills, and strengthen throat and neck muscles. Goals also may include coordinating treatment programs with other professionals or referring patients for other treatments. For example, a patient with a swallowing disorder may benefit from the collaborative care of a speech language pathologist and a medical doctor.

5.5.3 Scope of Speech therapy Speech Therapy is an Allied Health Science subject. Medical advancement in this field, awareness of the need for early intervention etc has increased the scope of Speech Therapy. A number of Speech Therapy courses are available now in India and abroad. Speech Therapy has its necessity in teaching and training children with intellectual disability.

5.5.4 Types of Speech, Language and Hearing Disorders The most intensive period of speech and language development is during the three of life a period when the brain is developing and maturing. There skills appear to develop best in a world that is rich with sounds, sights, and consistent exposure to the speech and language of others. At the root of this development is the desire to communicate or interact with the world. The beginning sign of communication occur in the first few days of life where in infant learns that a cry will bring food, comfort, and companionship. Research has shown that by 6 months of age, most children recognize the basic sounds of their native language.

5.5.4 (a) Speech and Language Disorders A speech disorder refers to a problem with the actual production of sounds. A language disorder refers to a problem understanding or putting words together to communicate ideas. Speech disorders include:

1. Articulation disorders: difficulties producing sounds in syllables or saying words incorrectly to the point that listeners can't understand what's being said.
3. Fluency disorders: problems such as stuttering, in which the flow of speech is

179 interrupted by abnormal stoppages, partial-word repetitions ("b-b-boy"), or prolonging sounds and syllables (sssssnake).

4. Resonance or voice disorders: problems with the pitch, volume, or quality of the voice that distract listeners from what's being said. These types of disorders may also cause pain or discomfort for a child when speaking.

Language disorders can be either receptive or expressive:

1. Receptive disorders: difficulties understanding or processing language.
2. Expressive disorders: difficulty putting words together, limited vocabulary, or inability to use language in a socially appropriate way.
3. Cognitive-communication disorders: difficulty with communication skills that involve memory, attention, perception, organization, regulation, and problem solving.

5.5.4 (b) Hearing disorders There are four types of hearing loss: ? Auditory Processing Disorders ? Conductive ? Sensorineural ? Mixed.

Auditory Processing Disorders Auditory Processing Disorders occur when the brain has problems processing the information contained in sound, such as understanding speech and working out where sounds are coming from.

Conductive Hearing Loss Conductive Hearing Loss occurs when there is a problem with the Outer or Middle Ear which interferes with the passing sound to the Inner Ear. It can be caused by such things as too much earwax, Ear Infections, a punctured eardrum, a fluid build-up, or abnormal bone growth in the Middle Ear such as Otosclerosis. It is more common in children and indigenous populations. Surgery and some types of hearing technologies can be used to treat Conductive Hearing

180 Loss such as Bone Conduction Hearing Aids, Bone Anchored Hearing Devices and Middle Ear Implants.

Sensorineural Hearing Loss Sensorineural Hearing Loss occurs when the hearing organ, the Cochlea, and/or the auditory nerve is damaged or malfunctions so it is unable to accurately send the electrical information to the brain. Sensorineural Hearing Loss is almost always permanent. It can be genetic or caused by the natural aging process, diseases, accidents or exposure to loud noises such as Noise-induced Hearing Loss and certain kinds of chemicals and medications. Auditory Neuropathy is another form where the nerves that carry sound information to the brain are damaged or malfunction.

Technologies such as Hearing Aids, Cochlear Implants and Hybrid Cochlear Implants can help reduce the effects of having Sensorineural Hearing Loss. **Mixed Hearing Loss** A Mixed Hearing Loss occurs when both Conductive Hearing Loss and Sensorineural Hearing Loss are present. The sensorineural component is permanent, while the conductive component can either be permanent or temporary. For example, a Mixed Hearing Loss can occur when a person with Presbycusis also has an Ear Infection.

5.5.5 Speech and Language Intervention In speech-language therapy, a speech language pathologist will work with a child one- to-one, in a small group, or directly in a classroom to overcome difficulties involved with a specific disorder. Therapists use a variety of strategies, including: **Language intervention activities:** The SLP will interact with a child by playing and talking, using pictures, books, objects, or ongoing events to stimulate language development. The therapist may also model correct vocabulary and grammar and use repetition exercises to build language skills. **Articulation therapy:** Articulation, or sound production, exercises involve having the therapist model correct sounds and syllables in words and sentences for a child, often during play activities. The level of play is age-appropriate and related to the child's specific needs. The SLP will physically show the child how to make certain

181 sounds, such as the "r" sound, and may demonstrate how to move the tongue to produce specific sounds. **Oral-motor/feeding and swallowing therapy:** The SLP may use a variety of oral exercises -including facial massage and various tongue, lip, and jaw exercises - to strengthen the muscles of the mouth for eating, drinking, and swallowing. The SLP may also introduce different food textures and temperatures to increase a child's oral awareness during eating and swallowing.

General guidelines for interventions Selection of Specific goals Organizing all the gathered information Structure the environment Selection of relevant materials Transformation and adaptation of the material Use of object from the environment Maintenance of schedule Principles for therapy Highlighting new or relevant information Pre-organized information Trained rehearsal strategies Using over learning & repetition Training in natural environment Early Intervention Following proper schedule **5.6 Yoga and Play Therapy: Definition, Objectives, Scope and Intervention** **5.6.1 Meaning and Definition of Yoga** The word yoga comes from the Sanskrit root ' Yug' meaning to join on yoke, implying the integration (on joining) of every aspect of human being from the inner most to the external. Yoga is practical philosophy that aims at uniting the body, mind, and spirit for

182 health and fulfilment. The father of modern yogashashtra Patanjali Maharshi defines yoga as 'Yogaschitta Vrutti Nirodhaha' that is yoga is controlling the nature of the mind. The ultimate aim of this philosophy is to strike a balance between mind and body and attain self- enlightenment. To achieve this, yoga uses movement, breath, posture, relaxation and meditation in order to establish a healthy, lively and balanced approach to life. Though the exact origins of Yoga are unknown but Yoga is considered to be the oldest physical discipline in existence. Yoga, thus symbolizes balance in every area of life. Yoga is one of the six schools of ancient Indian Philosophy. It is the practice that enables one to achieve higher levels of performance, bringing out the hidden potentials from within. Systematic Yoga practice will increase the physiological and psychological well being. 5.6.2 Objectives of Yoga Yoga practice reduces tension, stress, anxiety, weakness, helplessness, fear, negative thoughts etc. Which are increasing day by day in this mechanical human life. It treats the prolonged diseases or deficiencies like diabetes, asthma, heart problems, pains, sprains, indigestion etc. and makes the body active and good looking. Yoga practice equips the practitioners with devotion, attention, and concentration and alertness in every activity that he does. He also discharges his responsibilities with dedication thereby get respect and honor at his work. Man can prove his life worth living by developing his self physically and psychologically that contribute for the development of spiritual instinct in him. As soon as one is habituated for yoga practice, there would be number of changes in his routine activities, habits, thoughts, food habits, behaviors etc. Improvement in balance is one of the major benefits of Yoga. Improved balance is referred not only to the sharp physical coordination but also to the balance between the left and right, front and back and high and low aspects of one's body. Along with a host of benefits, Yoga also helps in developing and attaining personal values. Yoga erases a variety of ills in human beings. These may range from feelings of frustration, persecution and insecurity. Yoga greatly helps in the development of personal values. Personal values are those values which an individual develops and lives by all through his life.

183 Yoga and social values are closely related to each other. Social values are a set of philosophy that an individual carries for all his life. Yoga possesses great power to inculcate those values that go a long way in making a man complete. Yoga helps an individual not only to realize his own self but also understand other issues around him/her. Yogic theory and practice lead to increased self-knowledge. Yogic practices like breathing and posture exercises help in attaining and maintaining health, physical and mental, and relaxation. The knowledge gained through Yoga is not simply that of the practical kind relating to techniques, but of a spiritual sort pertaining to grasping something about the nature self and other matters. 5.6.3 Scope of Yoga Therapy Yoga is certainly more than mastering its postures and asanas and increasing the strength and flexibility of body. It indicates towards healing of mind and body and attaining the state of self-enlightenment. It is said that in early periods when Yoga was just introduced, the main purpose was to heal community members and the practitioners act as religious mediators. Needless to say, practicing of Yoga includes the traditional aspects too such as practicing different poses, chanting of mantra, observing breathing habit and controlling thoughts coming to mind with the help of meditation. Today, it has been practiced for fitness, healthy body and mind, strength, flexibility, emotional well-being and much more. The main purpose of practicing Yoga is to taking control over the body, mind and emotional aspects. The cessation of bad thoughts creates a positive vibe around the person and makes him healthy overall. 5.6.4 Yoga Intervention Yoga is an ancient Indian practice which involves moving the body and training the mind to achieve balance and well-being. The purpose of traditional yoga is for each individual to be healthy, both physically and mentally, and able to reach his or her highest potential as a person. Yoga aim is to prepare the body for meditation through breathing and physical exercises. Yoga emphasizes body-mind wellness through postures or asanas which tone and strengthen our muscles and increase our flexibility. The different asanas, particularly the twists and inversions, stimulate internal organs, as well as the nervous system, and promote circulation in all the body's major organs and glands. Importance of yoga for children with intellectual disability 1. Helps to co-ordinate the activities of the mind and body.

184 2. Tends to reduce the distracted state of mind and helping the mind to deal on the present activity. 4. Helps to improve his adaptive behavior to a degree unobtainable before. 5. Actively increase the ability to concentrate on the present activity. 6. Aims at improving general health, concentration, self-reliance and social relationship of the persons with mental retardation. 6. Yoga has been tried as an adjunct in education of children with mental retardation and attention deficit hyperactivity disorder. 5.6.5 Definition of Play Therapy Play Therapy uses a variety of play and creative arts techniques (the 'Play Therapy Tool-Kit (TM)' to alleviate chronic, mild and moderate psychological and emotional conditions in children that are causing behavioural problems and/or are preventing children from realising their potential. The Play Therapist works integratively using a wide range of play and creative arts techniques, mostly responding to the child's wishes. This distinguishes the Play Therapist from more specialised therapists (Art, Music, Drama etc). The greater depth of skills and experience distinguishes a play therapist from those using therapeutic play skills. Play therapy utilizes play, children's natural medium of expression, to help them express their feelings more easily through toys instead of words. Association for Play Therapy (APT) defines play therapy as "the systematic use of a theoretical model to establish an interpersonal process wherein trained play therapists use the therapeutic powers of play to help clients prevent or resolve psychosocial difficulties and achieve optimal growth and development." In the textbook Play Therapy: The Art of the Relationship (2nd ed.), Landreth (2002) defined child-centered play therapy: A dynamic interpersonal relationship between a child (or person of any age) and a therapist trained in play therapy procedures who provides selected play materials and facilitates the development of a safe relationship for the child (or person of any age) to fully express and explore self (feelings, thoughts, experiences, and behaviors) through play, the child's natural medium of communication, for optimal growth and development.

185 5.6.6 Scope of Play Therapy Children are referred for play therapy to resolve their problems (Carmichael; 2006; Schaefer. 1993). Often, children have used up their own problem solving tools, and they misbehave. may act out at home, with friends, and at school (Landreth, 2002). Play therapy allows trained mental health practitioners who specialize in play therapy. to assess and understand children's (pia). Further. play therapy is utilized to help children cope with difficult emotions and find solutions to problems (Moustakas, 1997; Reddy, Files-Hall, & Schaefer, 2005). 13y confronting problems in the clinical Play Therapy setting, children find healthier solutions. Play therapy allows children to change the way they think about, feel toward, and resolve their concerns (Kaugars & Russ, 2001). Even the most troubling problems can be confronted in play therapy and lasting resolutions can be discovered, rehearsed, mastered and adapted into lifelong strategies (Russ, 2004). 5.6.7 Importance of Play therapy It is difficult for most children below age ten to eleven to sit still for sustained periods of time. Play therapy provides for children's need to be physically active. In play, children discharge energy, prepare for life's duties, achieve difficult goals and relieve frustrations. As children play, they are expressing the individuality of their personalities and drawing upon inner resources which can become incorporated into their personality. Virginia M. Axline (1974) who developed the child-centered play therapy asserted that: "A play experience is therapeutic because it provides a secure relationship between the child and the adult, so that the child has the freedom and room to state himself in his own terms, exactly as he is at the moment in his own way and in his own time. " Play therapy helps to actualize the ultimate objectives of elementary schools facilitating the intellectual, emotional, physical and social development of children from the learning opportunities and experiences offered in school.

186 5.6.8 Objectives of play therapy Develop a more positive self-concept Assume greater self-responsibility Become more self-accepting Become more self-directing Become more self-reliant Become more trusting of self Experience a feeling of control Become sensitive to the process of coping Develop an internal source of evaluation Engage in self-determined decision making 5.6.9 Intervention of Playas a therapy results in Developing a more positive self-concept Assume greater self-responsibility Become more self-accepting Become more self-directing Become more self-reliant Become more trusting of self Experience a feeling of control Become sensitive to the process of coping Develop an internal source of evaluation Engage in self-determined decision making 5.7 Therapeutic Intervention: Visual Arts and Performing Arts (Music, Drama, Dance, Movement and Sports) 5.7.1

Visual Arts and Performing Arts :

Art reflects human emotions and human beings spontaneously express their frame of

187 mind through various art forms. Thus the intellectual mind merges with the artistic streak, giving birth to art. The

visual arts are those creations we can look at, such as a drawing or a painting. For example Drawing, painting, sculpture, architecture, photography, film, printmaking. It also includes the decorative arts of: ceramics, furniture and interior design, jewellery making, metal crafting and wood working. The literature available for utilizing art education for exceptional students is generally addressed to art education teachers to use in their classroom. However, expanding the use of art in the education of children with special needs into general and special education is advantageous to these individuals. The art educator can evolve to be a resource and perhaps a liaison between the special and general educator. Thus, to improve the education afforded to students with special needs, art can act as a bridge between general, and art educators to enhance the communication and cooperation between these specialists. Creating a cohesive network between art educators, special and general educators, draws upon the unique perspective that each educator has that can help the others in bolstering special education programs. The visual arts are a powerful teaching tool that can enhance the cognitive, emotional and social development of children. Children in special education programs are particularly in need of the assistance that the arts can provide.

The performing arts range from vocal and instrumental music, dance and theatre to pantomime, sung verse and beyond. They include numerous cultural expressions that reflect human creativity and that are also found, to some extent, in many other intangible cultural heritage domains.

Music is perhaps the most universal of the performing arts and is found in every society, most often as an integral part of other performing art forms and other domains of intangible cultural heritage including rituals, festive events or oral traditions. 5.7.2 Music Therapy Music therapy is a well-established allied health profession similar to occupational and physical therapy. It consists of using music therapeutically to address behavioral, social, psychological, communicative, physical, sensory-motor, and/or cognitive functioning. Because music therapy is a powerful and non-threatening medium, unique outcomes

188 are possible. For individuals with diagnoses on the autism spectrum, music therapy provides a unique variety of music experiences in an intentional and developmentally appropriate manner to effect changes in behavior and facilitate development of skills. Music therapy may include the use of behavioral, biomedical, developmental, educational, humanistic, adaptive music instruction, and/or other models. Music therapy enhances one's quality of life, involving relationships between a qualified music therapist and individual; between one individual and another; between the individual and his / her family; and between the music and the participants. These relationships are structured and adapted through the elements of music to create a positive environment and set the occasion for successful growth. The interventions used in Music Therapy aid in fostering skills across the entire developmental spectrum for children with special needs. Music Therapists encourage a child's sense of exploration and wonder as they focus on the goals targeted in your child's Individualized Education Program (IEP). How Does Music Therapy Make a Difference with Young Children? Music stimulates all of the senses and involves the child at many levels. This "multi-modal approach" facilitates many developmental skills. Quality learning and maximum participation occur when children are permitted to experience the joy of play. The medium of music therapy allows this play to occur naturally and frequently. Music is highly motivating, yet it can also have a calming and relaxing effect. Enjoyable music activities are designed to be success-oriented and make children feel better about themselves. Music therapy can help a child manage pain and stressful situations. Music can encourage socialization, self-expression, communication, and motor development. Because the brain processes music in both hemispheres, music can stimulate cognitive functioning and may be used for remediation of some speech/ language skills.

189 5.7.3 Drama Therapy Drama therapy is the intentional use of drama and/or theater processes to achieve therapeutic goals. Drama therapy is active and experiential. This approach can provide the context for participants to tell their stories, set goals and solve problems, express feelings, or achieve catharsis. Through drama, the depth and breadth of inner experience can be actively explored and interpersonal relationship skills can be enhanced. Participants can expand their repertoire of dramatic roles to find that their own life roles have been strengthened. 5.7.4 Dance / Movement Therapy Dance/movement therapy, a creative arts therapy, is rooted in the expressive nature of dance itself. Dance is the most fundamental of the arts, involving a direct expression and experience of oneself through the body. It is a basic form of authentic communication, and as such it is an especially effective medium for therapy. Based in the belief that the body, the mind and the spirit are interconnected, dance/movement therapy is defined by the American Dance Therapy Association as "the psychotherapeutic use of movement as a process that furthers the emotional, cognitive, social and physical integration of the individual." Benefits of Dance and Movement Therapy: Dance Movement therapy can help children with special needs in varied ways and in all the areas of impairment. The benefits experienced are as follows: It helps in improving attention and concentration and thus helps in furthering education Dance as a way of expression of emotion enables children to express through movements It helps in forming better relation Due to liking towards repetitive movements, a therapist can repeat a movement pattern which the patient needs to learn and when they start imitating the movement vocabulary develops. This helps them in learning different patterns of movements required for daily life activities

190 Group sessions in dance movement therapy enables in developing social skills and communications of autistic person Doing a choreographed dance movement sequence in a series of sessions in a row helps in improving memory and recapitulation skills. Touch therapy helps in developing trust on others as well as helps in reducing sensitivity to physical contact and touch. Dance movement therapy helps in improving body image of an autistic person. Dance/movement therapists work with individuals of all ages, groups and families in a wide variety of settings. They focus on helping their clients improve self-esteem and body image, develop effective communication skills and relationships, expand their movement vocabulary, gain insight into patterns of behavior, as well as create new options for coping with problems. Movement is the primary medium dance/movement therapists use for observation, assessment, research, therapeutic interaction, and interventions. Dance/movement therapists work in settings that include psychiatric and rehabilitation facilities, schools, nursing homes, drug treatment centers, counseling centers, medical facilities, crisis centers, and wellness and alternative health care centers. Dance/movement therapy can be a powerful tool for stress management and the prevention of physical and mental health problems. Dance/movement therapists integrate the dancer's special knowledge of the body, movement, and expression with the skills of psychotherapy, counseling, and rehabilitation to help individuals with a wide array of treatment needs. Social, emotional, cognitive, and/or physical problems can be addressed through DMT via group and individual sessions in many different types of settings from hospitals and clinics to schools. The fact that dance/movement therapists are immersed in the language of the body, rather than focusing solely on the verbal, lends characteristics to their work that set it apart from other types of therapy. 5.7.5 Sports Activities for Children with Special Needs All individuals benefit from regular physical activity and children with special needs especially. Children with special needs are benefitted in the following ways from physical or sports activities. We can see improvements in muscle strength, coordination, and flexibility. Improve exercise endurance, cardiovascular efficiency, and possibly increased life expectancy .

191 Experience better balance, motor skills and body awareness. Will show improvement in behavior, academics, self-confidence and building friendships. Will have positive changes in their health, quality of life and boost to their self-esteem. Gets to experiences a sense of accomplishment and possibly the taste of winning or personal satisfaction. Experience increases in attention span, on-task behavior, and level of correct responding. Will increase appetite and improve quality or sleep. Will see a decrease in secondary health complications like obesity, high blood pressure, low HDL ("good") cholesterol and diabetes. Will find an outlet for their physical energy, will help them cope with stress, anxiety and depression. Sports and activities especially good for special needs children: Swimming Bicycling Soccer Football Handball Gymnastics Bocce (is a ball sport) Weightlifting Sports, especially fundamental and movement education based sports like gymnastics, provide tremendous benefits for children with special needs. Physical education programs can considerably improve the lifestyle of a disabled child and are highly recommended. These programs may help control obesity, promote activeness, increase a child's self- image and social skills, and increase motivation. The physical activity along with support,

192 rewards, and interaction can, among other benefits, be very helpful to these children and their families. Physical Improvements - Children suffering from cognitive disabilities are most likely going to suffer from physical impairments as well. These children have substantial problems with motor skills in areas such as hopping, skipping, and jumping. Involvement in gymnastics can help these individuals develop fundamental motor and physical fitness skills. Self-Esteem - Developing a sense of self-esteem and confidence is an extremely important part of special education. These children need to be involved in environments where they feel that they are contributing successfully to a group. Their abilities in all other skill areas will improve as a result of a positive self-image and confidence. Cognitive Benefits - The hands-on aspect of sports leads to cognitive skill improvement in children with disabilities and allows them to discover and access strengths that cannot be challenged in the traditional classroom setting. The inherent structure of sport, with its organization and rules, can be used as a learning tool for introducing and practicing self regulation and decision making skills. Additionally, children can learn verbal communication and interaction with peers through involvement in sport. Special Olympics The mission of Special Olympics is to provide year-round sports training and athletic competition in a variety of Olympic-type sports for children and adults with intellectual disabilities. This gives them continuing opportunities to develop physical fitness, demonstrate courage, experience joy and participate in a sharing of gifts, skills and friendship with their families, other Special Olympics athletes and the community. The Special Olympics is the only organization authorized by the International Olympic Committee to use the word "Olympics" worldwide. Athletes compete in 32 sports, including snowboarding, judo, cricket, soccer. The Special Olympics program Healthy Athletes offers 1.4 million free health examinations in more than 120 countries to athletes at Special Olympics competitions. Health professionals perform a full exam in the categories of podiatry, physical therapy, audiology, vision, dentistry, physical therapy and more and more. More than 3.1 million athletes from over 175 countries take part in the Special Olympics.

193 Special Olympics athletes are divided to compete in categories based on gender, age, and ability. The Special Olympics athlete oath is "Let me win. But if I cannot win, let me be brave in the attempt." Special Olympics World Games are held every two years, alternating with Summer and Winter Games. 5.8 Let us Sum Up 1. "Occupational therapy is the art and science of directing man's participation in selected tasks to restore, reinforce and enhance the performance, facilitate learning of those skills and functions essential for adaptation and productivity, to diminish or correct pathology and to promote and maintain health." (Council of Standards, American Occupational Therapy Association, 1972). 2. An Occupational Therapist will aim to enable the child to be as physically, psychologically and socially independent as possible. Occupational Therapists work in close partnership with the child and their family, schools and other healthcare professionals. Together they have a shared responsibility for meeting the child's needs. In schools, for example, they evaluate the child's abilities, recommend and provide therapy, modify classroom equipment, and help the child participate as fully as possible in school programs and activities. 3. Occupational therapy interventions for people with intellectual disabilities are specifically adapted to the client with respect to the degree and type of support needed as well as the context. Interventions may include direct treatment as well as environmental adaptations, guidance, monitoring and counseling (including of the family, the educational staff, the clinical staff, employers and others). 4. Physiotherapy has scope in treating a wide range of conditions. It play an important role in all the branches of medical sciences, especially Orthopaedics, Paediatrics, Neurology, Cardio thoracic, Surgery, Sport Medicine etc. In set ups like leprosy, paraplegic and poliomyelitis after plastic surgery, burns clinics, spinal cord injury centres and in assistive devices manufacturing units etc. 5. A speech language pathologist sets broad but specific goals for each of his patients. Specific goals can include helping patients develop clearer speech, learn to use

194 alternate methods of communication, develop better reading and writing skills, and strengthen throat and neck muscles. Goals also may include coordinating treatment programs with other professionals or referring patients for other treatments. For example, a patient with a swallowing disorder may benefit from the collaborative care of a speech language pathologist and a medical doctor. 6. Yoga is one of the six schools of ancient Indian Philosophy. It is the practice that enables one to achieve higher levels of performance, bringing out the hidden potentials from within. Systematic Yoga practice will increase the physiological and psychological well being. 7. Music therapists involve children in singing, listening, moving, playing, and in creative activities that may help them become better learners. Music therapists work on developing a child's self-awareness, confidence, readiness skills, coping skills, and social behavior and may also provide pain management techniques. They explore which styles of music, techniques and instruments are most effective or motivating for each individual child and expand upon the child's natural, spontaneous play in order to address areas of need. 5.9 Check Your Progress A.1. What is the difference between Occupational Therapy and Physiotherapy? 2. Explain the objectives of the different therapies applicable for children with special needs? 3. Discuss about Dance and Movement Therapy. B.1. Discuss about the importance of yoga for children with special needs. 2. Prepare a short note on Therapeutic Application of Drama. C. After going through the Unit you may like to have further discussions on some points and clarification on other.

3 Netaji Subhas Open University From the Vice-Chancellor's Desk Dear Students, from this Academic Session (2015-17) the Curriculum and Course Structure of B. Ed.- Special Education have been thoroughly revised as per the stipulations which featured in the Memorandum of Understanding (MoU) between the Rehabilitation Council of India (RCI) and the National Council for Teacher Education (NCTE). The newly designed course structure and syllabus is comprehensive and futuristic has, therefore, been contextualized and adopted by NSOU from the present academic session, following the directives of the aforesaid national statutory authorities. Consequent upon the introduction of new syllabus the revision of Self Instructional Material (SIM) becomes imperative. The new syllabus was circulated by RCI for introduction in the month of June, 2015 while the new session begins in the month of July. So the difficulties of preparing the SIMs within such a short time can easily be understood. However, the School of Education of NSOU took up the challenge and put the best minds together in preparing SIM without compromising the standard and quality of such an academic package. It required many rigorous steps before printing and circulation of the entire academic package to our dear learners. Every intervening step was meticulously and methodically followed for ensuring quality in such a time bound manner. The SIMs are prepared by eminent subject experts and edited by the senior members of the faculty specializing in the discipline concerned. Printing of the SIMs has been done with utmost care and attention. Students are the primary beneficiaries of these materials so developed. Therefore, you must go through the contents seriously and take your queries, if any, to the Counselors during Personal Contact Programs (PCPs) for clarifications. In comparison to F2F mode, the onus is on the learners in the ODL mode. So please change your mind accordingly and shrug off your old mindset of teacher dependence and spoon feeding habits immediately.

I would further urge you to go for other Open Educational Resources (OERs) - available on websites, for better understanding and gaining comprehensive mastery over the subject. From this year NSOU is also providing ICT enabled support services to the students enrolled under this University. So, in addition to the printed SIMs, the e-contents are also provided to the students to facilitate the usage and ensure more flexibility at the user end. The other ICT based support systems will be there for the benefit of the learners. So please make the most of it and do your best in the examinations. However, any suggestion or constructive criticism regarding the SIMs and its improvement is welcome. I must acknowledge the contribution of all the content writers, editors and background minds at the SoE, NSOU for their respective efforts, expertise and hard work in producing the SIMs within a very short time. Professor (Dr.) Subha Sankar Sarkar Vice-Chancellor, NSOU

Let Us Sum Up 1.9 Check Your Progress 1.10

References 1.1 Introduction The developmental process of constructing knowledge and experience in such a way that it will increase the ability of the student to grow in spiritual and emotional maturity as well as in academic excellence. The prime aim of education has shifted to totality of experiences from acquisition of knowledge. As education is regarded as a dynamic process so the aim and objectives have changed. In order to justify the aims and objectives of a subject as well as a course it is essential to know what to teach. So vast is the field of sciences that it is no small problem to decide what facts should be taught. It is therefore very essential to develop or prepare or construct or organize curriculum which should meet the requirements of need of the society setting aims and objectives of the course. The curriculum is developed in different countries in different ways. 1.2

Objectives After going through this unit you will able to: 1. Explain the concept and types of curriculum. 2. Know about the various approaches of curriculum related to special education 3.

Describe about the

curriculum planning and the role of special teacher.

11 4. Narrate

core curriculum and expanded core curriculum for children with visual impairment. 1.3 Concept, Meaning and Need for Curriculum 1.3.1

Concept The term curriculum is

often used to describe only the goals, objectives, or plans, something distinct from the "means" of methods, materials, and assessment. Yet since each of these components are essential for effective learning-and since each includes hidden barriers that undermine student efforts to become master learners-curriculum design should consider each of them as a piece. On the other hand, according to secondary education commission curriculum much more than the boundaries by the academic subjects taught traditionally it should include

totality of experiences that a pupil receives

through manifold activities that go on in the school, in the classroom, library, laboratory,

workshop, playgrounds and in

the numerous informal

activities and connection between teachers and

pupil. But these guidelines apply to the general education curriculum which, when universally designed, should meet the educational needs of most students, including those with disabilities and also this document can help guide the design of expectations, content, methods, and outcomes across differing classrooms in each school or system. 1.3.2 Meaning The

term "curriculum" has different interpretations among scholars. According to Kelly (1999), curriculum is negatively viewed as a "syllabus which may limit the planning of teachers

to a consideration of the content or the body of knowledge

they wish to transmit

or a list of the subjects to be taught or both". In other words, simply convey subject knowledge is insufficient to be an effective curriculum. It should offer much more than a statement about the knowledge-content in order to be a productive curriculum. But in the Hong Kong Yearbook published in the year of 2006, curriculum is more positive in nature, which could achieve the objective of motivating learning, enhancing knowledge and abilities and developing positive values or even attitudes. These elements could help achieve whole-person development of students. These two ideas are polarized, yet they are not contradicted with each other in a sense that they just view curriculum in either macro or micro level. For the first one proposed by Kelly (1999), possibly he comments it in micro level. Undoubtedly, curriculum has the possibility of restricting what in-service teachers would like to teach in lessons. If the school tends to stick to the

12 curriculum suggested by the education department, its negative effect will become more explicit. Whereas in the Hong Kong Yearbook published in 2006, the commentator could evaluate the curriculum in macro level. Before 2000, still used traditional curriculum, which put emphasis on knowledge aspect instead of immersing other generic skills in the subjects, as the major guideline for schools except international ones. After 2000, the EDB started curriculum reform by inserting both generic and genetic skills in key learning areas in primary stage. Regarding secondary stage, the department attempts to achieve integrated curriculum. Students have to apply what they have learnt with various skills. In other western countries such as the US, the education department stresses the importance of merging skills to subjects so that students can apply them in authentic situations. With different timeframe and social values, the society will have different comments on the term "curriculum".

1.3.3 Need for Curriculum Curriculum has a broad scope because it is not only about the school, the learners and the teachers. It is also about the development of a society in general. In today's knowledge economy, curriculum plays a vital role in improving the economy of a country. It also provides answers or solutions to the world's pressing conditions and problems, such as environment, politics, socio-economics, and other issues on poverty, climate change and sustainable development. There must be a chain of developmental process to develop a society. The school curriculum particularly in higher education must be developed to preserve the country's national identity and to ensure its economy's growth and stability. For this reason

the need of curriculum as follows- (i) It helps to make the child interested in the process of learning. (ii) It provides enough scope to the child to learn the things at his own speed. (iii) It provides the child various opportunities of working in a group. (iv) It is need oriented. (v) It helps in development of a sound body. (vi) It gives a totality of experiences to the pupil. (vii) It helps to promote a democratic spirit in the child. (viii) It helps to create self-confidence in the child. (ix) It helps the child in making full utilisation of his leisure (

xi)

It sometimes leads to fatigue and boredom.

13 (xii) In groups, it becomes difficult to achieve the aim. Sometimes misunderstanding may lead to jealousy among the participants. In such cases it becomes the duty of the teacher to coordinate the activity and remove the misunderstanding. (xiii) Sometimes an activity may not suit all the members of a group and this leads to lack of interest in some students. (xiv) In the activity curriculum there is always a possibility that the participant may not be able to master anything those he knows something about various parts of the activity. (

xv)

The curriculum should be clearly understood. It specifies

not only the traditional subjects taught in school but it

includes

the

totality of experiences that peoples receive through the manifold activities that go on in the school, in the class room, library, laboratory, work shop, play grounds and in numerous informal contacts between

teacher and the

student. Thus

the whole life of the school becomes curriculum that can touch the life of the students at all points and help in evolution of balanced personality. (

xvi) Curriculum

should have flexibility and variety so that it can be easily adopted for different needs and interests. It will help to keeping away a sense of frustration that generally creeps in the child if any attempt is made to teach him uncongenial subjects. (xvii) The curriculum should be vitally and organically related to community life, interpreting for the child, its salient and significant features and permitting him to come in contact with some of its important activities. (activity curriculum). (xviii)

The curriculum should be such as to help to train the students not only for work but also for leisure. (xix) It should be framed in such a way that there exist as much of inter-relationship between different subjects and also between different topics in the same subject. It means that an attempt be made to keep the contents as "broad field" units so that it is easy to correlate than with life rather than narrow items of information.

But the students who have exceptional ability in health education and physical education, along with students who have a temporary or permanent disability (whether sensory, physical, social, or intellectual), require programmes that extend them, challenge them, and broaden their abilities. These groups of students need programmes adapted and organised to provide access to relevant opportunities, meet their individual needs, and contribute to the development of their awareness of their personal identity and their

14 sense of self-worth. So it must say that curriculum help these students as follows- ●●●● They are identified early ●●●● They have their learning needs addressed from the beginning, through relevant and consistent programmes ●●●● They work at their own pace ●●●● They work towards goals and face challenges that encourage them to develop to their full potential ●●●● They are valued by their peers, their teachers, the school, and the wider community ●●●● They help to plan programmes to meet their particular learning needs ●●●● They are included in regular lessons (and that resources or teaching approaches are adapted, as appropriate, to meet their special needs). Whereas the teachers who identify students with special needs should consult with parents, other teachers, and specialist educators before designing and implementing special learn programmes. Students with disabilities should be provided with means of access to all school facilities. And all the programme will be got success on the depend on

curriculum. 1.4 Curricular Approaches in Special Education- Developmental, Functional, Eclectic and Universal Design for Learning Approach 1.4.1

Meaning of

Curricular Apporaches:

There are varied approaches to development of curriculum. Some are common in both general and special education while some are more suited to

children with special needs. It is the responsibility of the teacher to select a suitable approaches or a combination of more than one approach with the aim to reach the student with the most suited curriculum and instructional process.

1.4.2

Developmental Approach The Developmental Approach Most developmental curriculum models have been derived from the work of Jean Piaget and his colleagues, who described cognitive development in children. Although individual models vary widely in the degree to which they

15 emphasize Piagetian principles, these models share several key concepts: 1. there is a sequence to mental growth. 2. This sequence is invariant. 3. Earlier steps in the sequence prepare for and provide the base for later steps. 4. This sequence is always in the direction of simple to complex and concrete to abstract. Although earlier stages of the sequence are prerequisite to later stages, they are never entirely displaced by them. When the developmental model is used to make curriculum content decisions, such decisions are typically based on the usual sequence by which without handicapped children develop. Thus, particular attention initially is paid to accurate assessment of the developmental level of the student. This is usually accomplished by use of the same standardized assessment tools utilized with general children. Once the student's initial developmental level has been determined, an educational program is designed to move him or her along the developmental continuum. Such a program is designed both to provide a variety of experiences related to a particular concept and to provide activities that are just slightly more advanced than the child's current level of functioning. As the child accommodates and assimilates new information, the activities are altered slightly so that the concepts presented are slightly beyond the comprehension level of the child, creating "disequilibrium" and providing a new challenge. Advantages Developmental theory provides the educator with information about the scope and sequence of normal child development. "While assimilation involves changing incoming information, accommodation involves changing the structures used to assimilate information". Brainerd also says that "perhaps the best way to think of . . . assimilation is as an interpretation of information that is made by the individual". Piaget meticulously documented the activities engaged in by children of various ages, and subsequent empirical studies have confirmed many of his observations. These observations provide the educator with a readily available body of information to use when making decisions about teaching strategies. According to developmental theory, this is important because educational activities "must not be too redundant with previous objects or events nor so novel that the child cannot assimilate them into his or her current cognitive organization. In fact, if objects or events are too different or novel, then the (child) may show distress or fear". Thus, one advantage of using developmental theory as the basis for making curricular content decisions is that the educator can be assured of providing the student with activities that appropriately challenge his or her cognitive and conceptual abilities. In addition, developmental theory holds that the optimal condition for generalization occurs when the discrepancy between a newly acquired skill and the existing skill repertoire creates a "just tolerable (conceptual) disequilibrium". This disequilibrium serves to maintain the student's interest by providing

16 a challenge, and at the same time it allows the student to compare new experiences with similar experiences already in his or her repertoire. Some authors have suggested that the generalization problems experienced by students with autism and other severe handicaps might be minimized if curricular content decisions were based on normal developmental sequences that ensure the appropriate degree of disequilibrium. Disadvantages although the developmental model makes the content debate: This is due in large part to the complexity of Piaget's writings, which are predominantly descriptive and theoretical in nature. The typical educator who attempts to make an applied "translation" of Piagetian theory into curricular content, therefore, faces a formidable task. One unfortunate strategy that has been used to translate Piagetian information into the classroom involves extracting items from developmental assessment tools and using them as the content basis for daily instruction. For example, many assessment tools contain tasks that require the child to find an item hidden under a cup as an indication of the child's acquisition of the concept of object permanence. Similarly, mean sends concept formation might be assessed by asking the child to pull on one end of a blanket in order to obtain a favourite toy placed on the other end. Unfortunately, educational programs often suggest that such activities should be included in the curriculum and taught to students who have "failed" these assessment items. This inappropriate use of developmental assessment information results in the teaching of isolated skills that are quite useless to students in the context of everyday life. Another problem in the use of developmental sequences is the misapplication of the principle that earlier stages are necessary prerequisites to later stages of development. The curricular sequences derived from this principle usually begin with skills acquired by very young nonhandicapped children and progress to more advanced skills that are typically acquired later. Unfortunately, this approach often means that students with autism are taught tasks appropriate only for young children, since they are "not ready" for more sophisticated tasks. This "slavish adherence to a developmental framework" has resulted in the production of hundreds of "pre-" curriculum programs (e.g., those labelled prevocational, preacademic, prehome, prelanguage, etc.).

Development cannot be forced or ignored. If we try and work more than one level of development beyond where the child is at it will just sound like nonsense and

they won't understand. If we try to push them to the next level they will keep returning to the previous one whenever they are stressed.

So we say

this model proposes that development of typical and atypical children progresses in a predictable sequence and that this sequence should be taught to students with disabilities. Several weaknesses are inherent in this approach for students with severe disabilities. First, time can be wasted working on skills which

17 may never be mastered. Second, not all behaviors in the sequence are necessary for independent functioning nor are they age appropriate as the child

grows well beyond the age that development skills are typically mastered. Finally,

the child is viewed as "developmentally young". Consequently, the activities and materials used for intervention continue to be less than age appropriate which leads to negative perceptions and low expectations for children with severe disabilities.

Unfortunately, the ultimate result is often that adults with autism, having never advanced past the "pre-" skills, have no alternative but to live in "prehomes" (institutions) and to work in "prejobs" (sheltered workshops).

A developmental approach to teaching and learning is simply put catering to the needs of the individual learner through an individualised program that works with their development long a range of measures: Cognitive - their brain readiness for mastery of existing concepts and introduction to new Curriculum challenges Physical - the physical gross and fine motor skills needed for a range of learning and social skills Moral Development - developing empathy and compassion Ego Development - understanding of the self in the world (e.g. time, space, self- reflection) Faith Development - belief in how their world is controlled (Ghosts and

monsters or logical reasoning)

Emotional and Social Development - self- awareness and self -management of emotions and working with others Self

Direction - understanding of learning needs and ways of working (learning styles and organisational skills) 1.4.3

Functional Approach The functional approach is considered to be the second paradigm of psychology. The idea focuses on the function of the mental processes which involves consciousness's. This approach was developed by William

James. What to give and how to give are two important questions which are to be answered before providing education to learner. The concept of curriculum has undergone changes in its meaning from time to time. The education

commission held the following view: functional

curriculum does not mean only the academicsubjects traditionally taught in the school, but it includes the

18

sum total of experiences that the child receives at school. At a given time period sometimes emphasis was given on character building, religious and moral values while at another times its objective was to make person a soldier, hence to

make a person physically capable for showing patriotism. In modern period more emphasis is given on earning bread

and butter. Due to this changing scenario one can find variety in the different basis of functional approach in curriculum development depending on the need of at that moment. On the other hand in second language acquisition functional

approaches are of similarities with Chomsky's Universal Grammar. Focus is on the of language in real

situations(performance) as well as knowledge(competence).A different writers have defined functional curricula or what is sometimes referred to as we skill instruction while there is a common theme imbedded in these and other perspectives

described in the literature, there is still a possibility of miscommunication when the term functional is used. The basic notion of functionality implies the usefulness of something for the user. Give that, it is clear that what is functional for

one person is not necessarily functional for another person or what is a functional use for an object in one situation may be functional in another situation. Functional curriculum must have a specific context and focus for children with

disability. A functional curriculum approach is a way of delivering instructional content that focuses on the concepts and skills needed by all the students with disabilities in the areas of personal, social, daily living and occupational adjustment.

What is considered a functional curriculum for any one student would be the content included in that student's curriculum or course of study that targets his or her current and future needs. These needs are based on a non-

discriminatory functional assessment approach. As we see

the philosophy of this approach is that students with severe disabilities need to acquire age appropriate and functional skills (

i.e., skills necessary for functioning independently). The major advantage of the functional approach to curriculum development

is that it reflects higher expectations for students with severe disabilities and promotes opportunities to acquire age-appropriate skills. The main weakness of this approach is that there are not established criteria for determining what is functional and relevant for an individual student.

The advantages of functional approaches are as follows: 1. Improve functional competence of children day-to-day living 2. Develops an independent level of functioning in all areas 3. Academic skills are incorporated when the children have ability to learn in them in the area of

functional reading, writing, arithmetic, time, money and other related skills.

19 4. Transfer of classroom learning to application of skills in natural environment is an important aspect of this curriculum. 5.

The teacher will choose practical training techniques and material used in daily living according to the task and functions he wants to teach the child in order to develop their functional competence in daily life children will participate fully in the learning experiences in or out of their classroom. 1.4.4 Eclectic Approach Philosophy of education can refer to either the academic field of applied philosophy or to any of educational philosophies that promote a specific type or vision of education, and/or which examine the definition, goals and meaning of education. Education and philosophy are closely inter-related. If philosophy is love of knowledge then education is acquisition of knowledge. For a long time education was regarded as a disciplinary process and learning by attempt was important for student. After that child-centered education laid an emphasis on presenting education according to the child's interest. Today these two contradictory forms come to a compromise. Interest has been admitted as the fundamental truth for attraction of the child, and once interest is created; even attempt would not be uninteresting to him. But neither is complete in itself; hence, co-ordination between two is necessary. The study of educational philosophy helps an educationalist to critically evaluate his own practices and make necessary changes in his practice. Philosophy has the potential for provoking revolutionary changes, revises and rejects some of our beliefs, develops analytical and logical skills and reasoning. Educational philosophy clarifies concept and analyses propositions, beliefs and theories of education. A philosophy vision is essential to understand the new trends in the educational systems especially the contemporary educational movement. Eclecticism has been derived from the verb root "elect". To elect means to choose and pick up. The good ideas, concept and principles from various schools of thought have been chosen, picked up and blended together to make a complete philosophy. Thus eclecticism is a philosophy of choice. Eclecticism is nothing but fusion of knowledge from all sources. It is a peculiar type of educational philosophy which combines all good ideas and principles from various philosophies.

Eclecticism is a conceptual approach that does not hold rigidly to a single paradigm or set of assumptions, but instead draws upon multiple theories, styles, or ideas to gain complementary insights into a subject, or applies different theories in particular cases. It can sometimes seem inelegant or lacking in simplicity, and eclectics are sometimes criticized for lack of consistency in their

20 thinking. It is, however, common in many fields of study.

We live in such an era when dogmatic adherence to a particular philosophy is foolish and is quite harmful. The world is changing very fast. Values are changing rapidly. We require a dynamic outlook and mental flexibility to have an all-round adjustment and optimal development. No philosophy contributes to all aspects of education. Idealism based on spirituality. Naturalism based on materialism. Pragmatism is between the two. While idealism is famous for its high and lofty aims of education, pragmatism is famous for its brilliant principles and curriculum, naturalism for its method of education. No philosophy is full-fledged to provide all things. But we want an integral education for complete living. If we synthesis all good ideas and principles with the best materials of all these philosophies we have to adopt an eclectic approach by harmonizing the conflicting ideologies and blend them together. We have to find unity in diversities through eclectic approach. Due to eclectic tendency, we find in modern education the influence of all the philosophies and tendencies of education. According to his doctrine of naturalism, Rousseau emphasized child-centered education. In modern education also child is developed according to his nature. Pestalozzi has stated that education is the development of the inherent capacities of a child and as such education should develop to the fullest extent the physical, mental and moral capacities of a child. After Pestalozzi, Herbart declared moral character as an aim of education and emphasizing curriculum construction advocated five formal steps of teaching. The third protagonist of psychological tendency, Froebel, insisted that educational process should follow the laws of Nature and considering the child's nature as good emphasized that education should allow complete development of the child through self activity. He argued for a free and unfettered environment for the development of the child and inculcation of sociability. After the advent of psychological tendency, the stage was occupied by scientific tendency. Herbert Spencer insisted that for complete living scientific subjects should occupy a prominent place in the curriculum. He tried to correlate education with actual life and uphold the importance of individualism. But we see that sociological tendency in education developed out of scientific tendency. According to sociological tendency, education is required to create such socially citizens who do not prove parasite on others but lead a life of self-reliance. For this purpose emphasis for vocational, technical and universal education began to given. Eclectic tendency has also exercised its influence in the solution of those problems which seemed, at one time, very complex and insoluble. This tendency has brought about a synthesis between the individual and social aims. Both the aims are not contradictory but complimentary and mutually contributory. Another problem to be tackled in the field of education has been of 'interests' and 'efforts'. In ancient times,

21 there ruled the disciplinary concept of education which upheld the use of 'efforts' in utter disregard of the child's interests. Hence, subjects were given importance with a view to their difficulty and efforts of children to learn them. Due to eclectic tendency both the factors, interests and efforts, are brought together to form a harmonious synthesis of the two to emphasize that a child needs the use of both, the interests as well as efforts, for his fullest development. The third problem is of 'freedom' and 'discipline'. The burning question had been how much freedom and how much discipline, should be provided and enforced. Eclectic tendency has solved this problem quite satisfactorily. Today freedom and discipline, stand integrated as one concept, as two sides of the same coin. Today the hard, rigid and expressionistic concept of discipline stands discredited and through impressionistic and sublimation processes, self-reliance, obedience, self-confidence, self-planning and managing are inculcated in children. This leads to self-discipline. Today freedom means all conducive opportunities for self-development and allowing the same opportunities to other as well. This is possible when each individual adheres to self-discipline and allows others the same rights for self-development through self-efforts, self-experiences and self investigation of new truths. Modern progressive education contains all the essential merits of all the philosophies and tendencies of education. The credit of this synthesis and unified integration goes to eclectic tendency. Philosophy of life has a powerful impact on education. Because eclectic tendency is gaining wider appreciation and acceptance in the life of an individual today, therefore the influence of this tendency on this education is natural. It reflects a harmonious synthesis of all those dynamic ideals and principles. Under the influence of eclectic tendency, all the previous ideologies and tendencies are influencing the following aspects of education. The question has always been arising whether the aim of education is to educate the child for society or for individual progress. The aim of modern education has become individual progress and development and social service. We have seen in the philosophy of Nunn that there is no difference between individual and universal progress. Here comes the role of eclectic tendency. If we look into Prof. Horne's definition this tendency becomes quite evident. According to him, education is a high adjustment of a physically and intellectually developed conscious individual to his intellectual, emotional and volitional environment. In this definition perfect fusion of psychological, scientific and sociological tendencies. Teaching material is no more an important matter, the earning of which should be compulsory for the students, as it is a truth or combination of truths. Modern teaching material is a brief form of civilization and a record of the standards of progress and values of civilization. The civilization of one period cannot be suitable to

22 another period; therefore, it would have to be changed on the basis of needs and changes. Teaching material is helping student to familiarize themselves with life as teaching is the preparation for life. Therefore, the process of knowing life would also remain changing. Method of teaching is used in order to experiment this material of civilization on the child and to bring desirable changes. This method should be used naturally by the teacher. The knowledge of children, knowledge of modern interests and problems, suppressing the rigid method of teaching and taking the broader meaning of teaching method-all these are symbolical of the teacher's ability. Therefore, a teacher should have knowledge of every method. The burden of the modern teacher has increased because he has to apply new methods with a view to the children's knowledge for the changing age, and the progress of the society. Regarding the method of teaching the kernel of all philosophy is 'method' according to 'circumstances', taking in view the interest of the child. Their emphasis is on motivating instruction, which is the result of the curriculum growing out of the present experiences of children. They have assigned a place for drill and concede the supreme importance of freedom both as an end and as a means to achieve the end. Among method they have a special advocacy for problem solving, which they believe, is on consonance with life's demands. Importance of direct experience is recognized by lending their support to 'play-way' and 'learning by doing'. The above mentioned eclectic tendency is visible not only in the field of education but in every field of education. This tendency is carrying us to a good age where we would be able to establish new ideals, values and standards over narrow and corrupt feelings. With regard to discipline none of the schools of the philosophies supports 'pressionism'. Freedom or free-discipline is their keyword. All the philosophers wish the mature children to play their part in making decisions about the affairs of the schools. They should not be pushed around against their consent. Discipline through knowledge and knowledge through experience is the under-current of all educational philosophies. The teacher's role as a friend, guide, and philosopher, the director of the class, arranger of the experiences to the child, etc. is prominent in modern educational scene. Under the influence of eclectic tendency more and more teacher-training institutions are being opened to provide training to teachers for various grades and levels of education. In ancient and medieval times, provision of education was made by religious institutions. But, under the influence of eclectic tendency, modern education has broken off from religious bonds and has become material and worldly. Under the influence of sociological tendency, the function of school is to prepare dynamic citizens to participate in the social activities successfully. As such, school is now regarded as a miniature society to develop dynamic, enterprising and resourceful citizens. Above discussion makes it

23 crystal clear that modern education has drawn from all the tendencies namely- psychological, scientific and sociological to a very great extent and this process of synthesizing and gainfully imbibing is known as eclectic tendency. It is the nature of man that he likes change. He wants new and novel ways in every field of work. The same is the case with learning process. Learners always like something new and exciting. This approach is broad and may include every kind of learning activity and saves learner from monotony. It is more appropriate

for Pre School learning but not less beneficial in the class rooms. It is helpful in all kinds of skills in stimulating a creative environment and gives confidence

to the learners. In this approach children discovers and in still

good ways of learning. Above all this approach gives a chance to our common sense to mould and shape our method according to the circumstances and available materials of teaching aids.

There may be gaps in learning, if you are frequently switching curriculum. This approach can lack disciplined learning and allow for laziness. Without grabbing to one approach, curriculum choices and overall directions can be confusing and overwhelming. The conception of education today is very broad and that our educational thinking in its totality has been affected not by one single philosophical thought or tendency but by the cumulative experience of past generations in the field of education. Our educational ideals and practices may consequently be traced to various sources all of which have been harmoniously blended to determine the present-day educational principles and practices.

Eclectic approach is a method of language education that combines various approaches and methodologies to teach language depending on the aims of the lesson and the abilities

of the learners. Different teaching methods are borrowed and adapted to suit the requirement of the learners. It breaks the monotony of the class.

The teacher has more flexibility. No aspect of language skill is ignored. There is variety in the classroom. Classroom atmosphere is dynamic.

In eclectic approach, the teacher can choose from these different methods and approaches: ●●●● Grammar-translation Method: It is a method of teaching languages by which students learn grammatical rules and then apply those rules by translating between the target language and the native language. ●●●● Direct Method: In this method the teacher refrains from using the students' native language. The target language is directly used for teaching all the four skills- listening, speaking, reading and writing. ●●●● Structural-situational Approach: In this approach, the teacher teaches language through a careful selection, gradation and presentation of vocabulary items and structures through situation based activities.

24 ●●●● Audio-lingual/Audio-visual Method: In this style of teaching students are taught through a system of reinforcement. Here new words and grammar are directly taught without using the students' native language. However, unlike direct method, audio-lingual method does not focus on vocabulary. Instead, the teacher focuses on grammar through drill and practice. ●●●● Bilingual Method: The word 'bilingual' means two languages. In bilingual method, the teacher teaches the language by giving mother tongue equivalents of the words or sentences. ●●●● Communicative Language Teaching: This approach lays emphasis on oral method of teaching. It aims to develop communicative competence in students. ●●●● Total-Physical Response: It is based on the theory that memory is enhanced through association with physical response. ●●●● The Silent Way: In this method the teacher uses a combination of silence and gestures to focus students' attention. 1.4.5

Universal Design for Learning Approach

Universal Design for Learning is

an educational framework based on research in the learning sciences, including cognitive neuroscience that guides the development of flexible learning environments that can accommodate individual learning differences.

Recognizing that the way individuals learn can be unique, the universal design for learning framework, first defined by David H. Rose, in the 1990s, calls for creating curriculum from the outset that provides: multiple means of representation to give learners various ways of acquiring information and knowledge, multiple means of expression to provide learners alternatives for demonstrating what they know, and multiple means of engagement to tap into learners' interests, challenge them appropriately, and motivate them to learn. Curriculum, as defined in the universal design for learning literature, has four parts: instructional goals, methods, materials, and assessments.

Universal design for learning

is intended to increase access to learning by reducing physical, cognitive, intellectual, and organizational barriers to learning, as well as other obstacles.

Universal designs for learning

principles also lend themselves to implementing inclusionary practices in the classroom. Universal Design for Learning is referred to by name in the Higher Education Opportunity Act of 2008 (Public Law 110-315). It is also mentioned in the 2004 reauthorization of the Individuals with

25 Disabilities Education Act (IDEA),

which in

turn refers to a legal definition of the term in the Assistive Technology Act of 1998. The emphasis being placed on equal access to curriculum by all students and the accountability required by IDEA 2004 and No Child Left Behind legislation has presented a need for a practice that will accommodate all learners.

The concept and language of Universal Design for Learning was inspired by the universal design movement in architecture and product development, originally formulated by Ronald at North

Carolina State University. Universal design calls for "

the design of products and environments to be usable by all people, to the greatest extent possible, without the need for adaptation or specialized design". Universal design

for learning

applies this general idea to learning: that curriculum should from the outset be designed to accommodate all kinds of learners. Educators have to be deliberate in the teaching and learning process in the classroom (Preparing class learning profiles for each student). This will enable grouping by interest. Those students that have challenges will be given special assistance. This will enable specific multimedia to meet the needs of all students. However, recognizing that the UD principles created to guide the design of things (e.g., buildings, products) are not adequate for the design of social interactions (e.g., human learning environments), researchers at CAST looked to the neurosciences and theories of progressive education in developing the universal design for learning principles. In particular, the work of Lev Vygotsky and, less directly, Benjamin Bloom informed the three-part universal design for learning framework. Some educational initiatives, such as Universal Design for Instruction (UDI) and Universal Instructional Design (UID), adapt the Mace principles for products and environments to learning environments, primarily at the postsecondary level. While these initiatives are similar to universal design for learning and have, in some cases, compatible goals, they are not equivalent to universal design for learning and the terms are not interchangeable; they refer to distinct frameworks. Despite the popularity of universal design for learning among educators and disability support professionals, little research has been conducted to evaluate its effectiveness as a model of good pedagogy. However, a number of studies have appeared in recent years, providing preliminary data in support of this instructional model. For example, a recent study at Colorado State University found "recognizable changes in instructor behaviour" from only a few hours of training in universal design for learning principles and teaching practices. The same study described the creation of a research questionnaire for students and instructors, based on universal design for learning's three principles. Universal design for learning can be used in the support of students with disabilities and as well as learning differences. In actual case studies conducted by Elizabeth McAra-

26 Craford applying Universal Design principles expands the ability of students to access needed supports in post-secondary settings. Universal design for learning presents information in ways that adapt to the learner, instead of asking the learner to adapt to the information. This is good for kids with learning and attention issues because it gives them more than one way to interact with material. Universal design for learning can make it easier for kids to use their strengths to work on their weaknesses. To understand what Universal Design for Learning is, it helps to understand what it's not. The word "universal" may throw you off. It may sound as though universal design for learning is about finding one way to teach all kids. But universal design for learning actually takes the opposite approach. The goal of universal design for learning is to use a variety of teaching methods to remove any barriers to learning and give all students equal opportunities to succeed. Universal design for learning doesn't specifically target kids with learning and attention issues. It's about building in flexibility that can be adjusted forever student's strengths and needs. Even if you're not familiar with the phrase "universal design," you've most likely encountered many examples of it in your everyday life. Closed captions, automatic doors and accessibility features on smartphones are all examples of universal design. These design elements help people with disabilities. But people who don't have disabilities may also want to use them. Universal design for learning provides that same kind of flexibility in the classroom. The goal of universal design for learning is to present school subjects so that all learners can access the information, and to give learners different ways to demonstrate their knowledge. Universal design for learning is based on three main principles: ●●●● Representation: universal design for learning offers information in more than one format. For example, textbooks are primarily visual. But providing text, audio, video and hands-on learning gives all kids a chance to access the material in whichever way is best suited to their learning. ●●●● Action and expression: universal design for learning

gives kids

more than one way to interact with the material and to show what they've learned. For example, teachers can assess students using pencil-and-paper

tests, oral presentations or group projects. ●●●● Engagement:

universal design for learning

looks for different ways to motivate students. Letting kids make choices and giving them assignments that feel relevant to their lives are some examples of how teachers

can

sustain students' interest. Other common strategies include making

skill building

feel like a game and creating opportunities for students to get up and move around

the classroom.

27 1.5

Types of Curriculum- Need Based, Knowledge Based, Activity Based, Skill Based and Hidden Curriculum 1.5.1

Meaning for Types of Curriculum

Since curriculum reflects the models of instructional delivery chosen and used, some might indicate that curriculum could be categorized according to the common psychological classifications of the four families of learning theories "Social, Information Processing, Personalist, and Behavioural." Longstreet and Shane have dubbed divisions in curricular orientations as: child-centered, society-centered, knowledge-centered, or eclectic. Common philosophical orientations of curriculum parallel those beliefs espoused by different philosophical orientations - Idealism, Realism, Perennialism, Essentialism, Experimentalism, Existentialism, Constructivism, Reconstructivism and the like. Whatever classification one gravitates to, the fact remains that at one time or another curriculum in the United States has, at some level, been impacted by all of the above. In essence, American curriculum is hard to pin down because it is multi-layered and highly eclectic.

Anything and everything that teaches a lesson, planned or otherwise. Humans are born learning, thus the learned curriculum actually encompasses a combination of all of the following - the hidden, null, written, political and societal etc. Since students learn all the time through exposure and modelled behaviors, this means that they learn important social and emotional lessons from everyone who inhabits a school -

from the janitorial staff, the secretary, the cafeteria workers, their peers, as well as from the department, conduct and attitudes expressed and modelled by their teachers.

Many educators are unaware of the strong lessons imparted to youth by these everyday contacts. 1.5.2

Need Based Curriculum Curriculum is the most challenging field of study, since after one century of its formal existence as a scientific field of study, there is not, yet, any agreement among the specialists and experts about the elements and dimensions and even the concept of curriculum. Curriculum needs assessment as a part of curriculum, has, also, the same problem and there is not, yet, any stable conception of this definition, in spite of its extensive application, its utilization for justification of importance and necessities of curriculum and changing needs assessment into a principle for distribution of facilities and sources in connection with different projects. Ambiguity in needs definition led many bias - accepted studies to fail in presentation a comprehensive conception of needs. Some of

28 the specialists like Mattimor and Knudson can use some alternative definition such as "situation assessment", and "situation Analysis" and also, some other specialists like Kliaton believed that the term "needs" must be deleted from the literature of education. This reveals that how challenging needs conception may be. We can introduce, however, the most important needs - definition as following: 1. "Needs" as a want or preference: In the first conception, some people may believe that "needs" is the equivalent of one's want or one's preference. This definition of "needs" which is sometimes called "democratic conception," respects the views of majority of people about a specific subject. None the less; this conception has been criticized because of three reasons first of all, because the people's views are considered to be subjective, secondly, people are not awarded of their real needs and thirdly since the needs concept is not the same as want concept. 2. "Needs" as a deficit or as a problem: In this regard, need is a kind of deficit or a kind of problem in a particular field which is innately harmful. Shriren advocates this definition which is referred as problem - approach. In this view, 'need' implies the situation in which minimum satisfactory level is not attained. The concept of minimum satisfactory level is ambiguous and arguable, since this term is used in some fields such as biology and medicine but there is no evidence in education for it. 3. "Needs" as a gap or as a discrepancy: In the third and the most acceptable conception "needs" is considered as the discrepancy between the present situation and the ideal situation, for instance Kaufman defines needs as a gap between current outcomes and expected outcomes and in this kind of definition, there is a distinction between 'needs' and 'semi needs'. Needs are in relation to outcomes. Whereas, semi needs are in connection with the means of achieving needs and only after determining needs, one may identify the means of achieving them. As a conclusion, each of the above definitions looks at the needs and needs assessment through a particular point of view. I believe that each of the definitions, depending on the situation, has effective application and one should use situational approach in connection with their application. To have an easier study, the development of curriculum needs assessment will be discussed in both formal and in informal periods. Informal period is any time of studying curriculum in which needs assessment is not a particular domain and in some extent is not distinct from other curriculum discussions. Formal period of curriculum is the time through which curriculum specialists can specify and identify the limitations of needs assessment compared with other domains. A general historical study of education shows that in an informal period needs studying is closely related to the development of objectives and information sources. As Tanner mentioned, the emerging curriculum field was being buffeted by conflict and disputation between the traditional subject-centered approaches, based upon about adult demands and child-centered approaches in curriculum making decisions. Because of considerable social changes, another group called, social behaviourists were added to the previous battling groups. They were the pioneers of paying attention to the society and its basic needs and they, also, emphasised on the curriculum effectiveness as a means of solving life problems. This conflict which were at the maximum point in 1910s, made such a history of curriculum in which every other time one of the battling views was dominant. The first systematic study of curriculum was published in 1902 under the title of "the child and the curriculum" by Dewey and he identified three basic learning factors such as learner (the immature, undeveloped being), society (values and adult's objectives) and subject matter as the main factors of educational process. Bobbitt in 1918 wrote the book "the curriculum" considered needs studies and proposed a model under the title of "activity analysis". Because Bobbitt believed education should prepare children to be productive adults, he focused on adult life as the source of curriculum needs assessment. Based on such analysis, he produced a list of over 900 objectives, some of which were to be the starting point for the school curriculum. After these views, from 1933 to 1944, a study entitled eight years study was conducted. Researchers in this study developed a model based upon the following three fundamental resources; 1) the social demand approach, 2) the adolescent - needs approach, and 3) the specialized subject matter approach. The necessity of considering psychological needs, gradually, was expected in curriculum. This procedure was started with Sigmund Freud and continued with the views of William Featherstone (1950), Abraham Maslow (1954), Danial Prescott (1963), and Erikson. They were the advocates of considering psychological needs in curriculum (unruh and unruh, 1998). Psychological needs were added to the curriculum in 1950s and, therefore, curriculum needs assessment got very complicated. The publication of "Basic Principle of Curriculum and Instruction" by Ralph Tyler in which he presents his rational model of curriculum, brought about a new prospective for curriculum. Besides emphasizing on triple data sources (society, learner and subject matter), he makes a

30 distinction between psychological needs and educational needs. He believes that psychological needs are not in the domain of curriculum. In the psychological needs conception, "needs" means not having equilibrium whereas, the task of curriculumist is considering 'needs' as a gap, or discrepancy, on educational needs. As it is stated up to this stage of curriculum history, though there has been many efforts in curriculum needs assessment studies, these efforts didn't consider needs assessment as an independent domain of curriculum field. Hilda Taba the popular curriculum specialist, extended the Tyler's rational and consequently, introduced needs assessment as an independent stage in curriculum process. She emphasized on seven stages of curriculum and called the first stage, "Diagnosis of needs" Making a distinction between educational needs and psychological needs, in spite of Tyler's view, She believed that one should almost consider psychological needs, and at least, psychological problems must not be considered in curriculum deeply, though the primary objective of curriculum is considering educational needs. Feuerstein, also, for conceptualizing of curriculum stages, has discussed eleven stages that begin with the related diagnosis of needs. From now on, in the literature of curriculum in relation to needs assessment, some independent studies were begun and some models were proposed for it. For instance, discussed two different models which show the position of needs assessment in curriculum. In one conception, curriculum is started with needs assessment and, then, is followed by developing general goals and in another model "needs study" is postponed to a stage after developing general goals which are needs, mission, statement, specific objectives, learning activities, Evaluation and mentoring. Studying the development of needs assessment curriculum, one can conclude the followings: ●●●● There is no agreement on the position of needs assessment in curriculum, particularly; the question that whether needs assessment is the first step of curriculum or it is an approach that takes place after developing the objectives. ●●●● All the proposed models share needs assessment at the stage of curriculum development. All the above mentioned models, accompanied with basic variables of data sources are to drive objectives and develop other elements based on such policies. However, some recent studies, also, prescribe considering needs assessment at the stage of implementing curriculum. For instance, those models that reject linear sequences, avoid any Preparation for curriculum, and made curriculum decision through student-teacher participation process in the classroom

31 and through student interests, all advocate this theory. For instance, Macdonald view, depending on Emergent curriculum advocates the necessity of studying curriculum problems including needs assessment at the implementing stage. As a consequence, one can consider the procedure and historical development of curriculum as a static phenomenon and considers need assessment at the developing stage. However; this situation questions the dynamic state of this scientific domain and, therefore, it is necessary to consider needs assessment at the implementation stage. ●●●● History of curriculum shows numerous ideological conflicts in connection with basic data sources and each of the sources has particular advocates, whereas the Tyler's rational (assembling sources in curriculum studies), is dominant in curriculum. It seems one should follow more innovative approach in using data sources and it is not enough to value, equally all the three data sources originating from different ideological conceptions. ●●●● The distinction between psychological needs and educational needs, also, brings about a sort of ambiguity, however, some specialists put emphasis on psychological needs whereas some others emphasize on the educational needs. Furthermore; needs assessment participants, needs assessment mechanisms and methods, the way of utilizing needs assessment outcomes and some other things are not, yet, obviously stated.

1.5.3 Knowledge Based Curriculum

Knowledge based learning on the other hand

aims to build upon the knowledge that the pupil already has. There are clear learning objectives set out which link to the activity undertaken; helping the child to see how their existing knowledge will help them to complete the task. Clear guidelines will be set at the beginning of the task which helps the learner to see a clear path to the finish. Along the way they can apply the knowledge they already have, whilst also learning new things. This linear structure helps the pupil to see how they are progressing and can help to highlight where, if any, the gaps are in their knowledge. Using this method, regular feedback is given to help the children know where they have gone wrong and where they are correct. This means that their learning is assessed along the way ensuring that they are making progress. Learning a lot of facts at once can be confusing for children, especially when they have a range of subjects to learn, so it is

important to use the knowledge based technique as it means

32 you can easily pin-point where more focus is needed. By drawing on the knowledge a child already has it boosts their confidence as it proves to them that they already have some, if not all, the information they need to complete the required task.

And even if they don't, they know where they need to put more focus. For teachers this can mean having more one to one time with pupils to talk through how they are ending the task/ subject and giving any additional help they may need. This can seem time consuming but it will ensure that all pupils are engaged and learning during the lessons, and that they will all succeed.

The National Council for Accreditation of Teacher Education (NCATE) has established standards designed to ensure that teacher education programs maintain high academic standards and that program graduates are of a high quality. To achieve these goals the organization has developed a process whereby professional expectations are developed and promulgated through published standards and monitored by peer review. An examination of NCATE standards provides insights into areas of teacher education perceived to be in need of attention from a national perspective. The 1987 standards reflect an effort to improve professional education by encouraging experimentation and innovation in institutional planning. Current standards focus upon the inclusion of broad knowledge bases that are developed from sound theories and scholarly inquiry. By mandating that each accredited unit develop a teacher education program founded upon broad knowledge bases, NCATE is effectively requiring some teacher education programs to alter current curricula and practices. Historically, some teacher education programs have been experience based. Rather than focusing instruction upon pedagogical theories and research, these programs tend to transmit folkways from one generation to the next through faculties' stories and clichés. Current NCATE standards, however, require that accredited teacher education programs be "based on essential knowledge, established and current research findings, and sound professional practices" NCATE standards further mandate that each program be coherent from an explicitly stated philosophy through the measurements of program outcomes. This coherency must be achieved through faculty collaboration and be reflected in: "curricular design and planning; course syllabi; instructional design, practice, and evaluation; students' work; use of major journals in the field by faculty and students; and faculty and students' (especially graduate students) participation in research and synthesis,". The faculty of each teacher education unit must collaborate to develop a coherent curriculum that is founded upon a defensible knowledge base in order to receive accreditation. While the

33 standards clearly indicate the NCATE expectation, procedures used to achieve these must be developed and implemented by each teacher education unit. Prior to developing a process of identifying and implementing a teacher education program that will meet the spirit and intent of NCATE standards, a workable operational definition for knowledge base must be devised. A definition is noticeably absent from the NCATE (1986) glossary of terms. Wisniewski (1989) describes the knowledge base as the intellectual heritage of practitioners which is used to validate or challenge one's scholarship in professional endeavors. To meet NCATE standards each unit must develop an orderly process in institutional planning which identifies the knowledge, skills and attitudes that are needed by professional teachers. Additionally, the process must include provisions for faculty members to collaborate in developing a coherent and defensible knowledge- based curriculum. Any disagreement will necessitate a reconsideration of both elements of the model, philosophy, and goals. Both elements are tentative. When coherence between philosophy and goals is established, the process can continue. As courses are identified in the professional education sequence, care must be taken to ensure that each program goal has been assigned to a particular course and that no goal has been unnecessarily duplicated. This can best be accomplished by developing a matrix. Course Objective Proposed After the goals for each professional education course has been ascertained, faculty members will propose tentative objectives for each goal assigned to their respective courses. At this point in the process, the program content is becoming quite specific and the knowledge base must be continually monitored to ensure program viability. The knowledge base is a set of rigid principles that determines the scope and sequence of an undergraduate teacher education program. Rather, it is a best- yet product derived from a continuous process of scholarly inquiry. In reality, the process used in determining the knowledge base for beginning teachers is as important as the product. New knowledge is continuously being produced as teachers and teacher educators practice philosophical reflection, develop new theories, find new answers using research, or make observation as they observe educational practices. While these processes yield new knowledge, not all of the knowledge can or should be included in the undergraduate teacher education program. To judge the knowledge that should be included in an undergraduate teacher education program, several questions need to be asked. The first criterion by which the knowledge should be judged is utility. Knowledge included in the undergraduate teacher education program should be useful.

34 The knowledge should be useful in guiding practices, in assisting teachers, in understanding the behaviour of children, or in assisting teachers to better understand the dynamics of the teaching and learning process. The second criterion by which knowledge included in the teacher education program should be judged is its comprehensiveness. An effective teacher education program must present alternative points of view to allow future teachers to evaluate the worth of competing theory bases and practices before making professional decisions. Third, the knowledge base that promotes understanding and perspective among students should be presented. The content, skills and attitudes presented, practiced, and encouraged should be structured in ways to ensure that students do not view the knowledge base as a set of rigidly prescribed steps to be followed, but rather as principles that may have application in a given situation. Beginning teachers must realize that an effective teacher education program helps prepare them to make professional decisions in accord with the conditions of a given situation. A fourth criterion is that knowledge should be included in the undergraduate teacher education program that assists students in developing more comprehensive theoretical bases. Specific elements of knowledge which fit into a larger theoretical base should be considered more valuable than a bit of knowledge that is unrelated to other knowledge. Fifth, knowledge should be included in the teacher education curriculum that is based upon and supported by research. Students should be taught that knowledge based upon experience is thinking an experience has value, but many errors can be made using experience as a primary determinant of professional behaviour. Students should be warned that experience-based decisions tend to lead to stimulus generalizations in which one experience principle will be used in times and situations that are totally out of context with the experience that precipitated its creation. Those objectives that can meet one of the five criteria can then be included in the appropriate professional education course on a tentative basis. This objective must further be found to be acceptable during the process of course development. Content derived from objectives that are included in a particular professional education course must be scrutinized from several perspectives. This examination is designed to ensure that the content taught is based upon a sound knowledge base and is not a way that students gain mastery on various experiences. Such type of projects should be completed under a problematic situation in a natural setting.

35 1.5.4

Skill Based Curriculum The drive for a skills based curriculum is more and more prevalent. How to deliver such curriculum remains a challenge for a number of schools. The key to success is not logistics. Two main structures support such drive. In one structure, the skill based curriculum is about mapping where the fundamental skills are delivered. It is a hidden skill based curriculum. This is the way to deliver the least changes in the 'traditional' curriculum. The key to success here is always whether this brand of curriculum is driven by the teachers (Cross curriculum work anyone?) or by a manager in his/ her office. You can guess which one is more successful. The other more honest structure represents the traditional 'circle within a circle approach'. The Welsh Bac and International Bac both use this structure to explain their curriculum. Put the core skills in the middle, surround those by the curriculum and you are done. It will work with the IB because they make sure it will. It will work with the Welsh Bac as it is integrated in the assessment structure. It does not always work when this circle is mirrored elsewhere. The key to success here is always a management issue. Does the management give itself the means to implement their skill based curriculum? When it represents just a fad or a marketing ploy, the skills which are supposedly at the heart of the curriculum are in fact peripheral to it. It is a traditional curriculum with added 'bits'. Whilst the departments (in secondary education) are mostly run as tight ships, the skills area is run by whoever is unlucky enough to be volunteered and delivered by whoever is available. It is a 'left over' approach. Surprisingly this has little impact on results (because it does not really improve any skill). If you are not in the market for the IB or Welsh Bac, you could do a lot worse than considering the EPQ as a cornerstone of your skill based curriculum post 16. The experience you will gain there will easily be transferable to KS3 and 4 later on. The project approach can be tailored to your curriculum needs and the support it requires can be integrated within the pastoral support. It can easily be the central component of your curriculum around which organise themselves the different curriculum areas. This will easily evolve in line with what your school requires, but at least you start from a solid base. You get your circle within a circle curriculum and the skills are clearly at the core

Skills based learning

centres around developing and applying specific skills that can then be used to obtain the required knowledge. The classroom environment will encourage independence, as well as combining active-learning and collaboration to help the children retain the knowledge. This process allows the pupils to 'access, process and then express' the knowledge they have learnt rather than simply writing

it
down.Tasks
36 can include working together to assess one another's knowledge and to help each other to progress and learn. This form of learning is effective for helping children improve their self-confidence, which in turn will help them to do well. It also means that they will be more receptive to other, possibly harder, subjects as they will feel they have the skills and ability to tackle the problems in front of them. It not only helps children to learn what they need to succeed in education, develop life skills that can help the child to grow and progress as a person as well. The main skills this way of learning will help are interaction and teamwork, as the children work together to solve problems and help each other to achieve the aims. From a teacher's point of view, it changes the way lesson planning is done. Whereas before the focus would have been on how they could teach the class about a certain topic, skills based learning means that the

focus is on how that topic can help the children to develop and learn certain skills. 1.5.5

Hidden Curriculum

Nowadays the term "Hidden Curriculum" is very popular but what does it really mean in school practice? Here are some of the most significant and meaningful definitions. "Hidden curriculum is a broad category that includes all of the unrecognized and sometimes unintended knowledge, values, and beliefs that are part of the learning process in schools and classrooms."¹ According to the Blackwell dictionary of sociology, "Hidden curriculum is a concept used to describe the often unarticulated and unacknowledged things that students are taught in school."² Moreover, the hidden curriculum generally refers to the "subtle or not-so subtle messages that are not part of the intended curriculum"³. In short, the term is used to "describe the unwritten, informal code of conduct to which children are expected to conform in the classroom". In other words, hidden curriculum refers to the unintended or implicit values cultivated in the practices exercised in the classroom and educational institutions through the application of the curriculum. For example, "Children are said to be rewarded not only for learning their subject curriculum but appearing to do so with enthusiasm, alertness, and deference to and respect for authority. In this way education imparts not only formal knowledge but an understanding of how to act 'properly' in wider society."⁴ Also, this can be associated with the instructional practices exercised in the classroom by teachers to cope with the demands of organizational structures over which they have little control as the "set of values, attitudes, knowledge frames, which are embodied in the organization and processes of schooling and which are implicitly conveyed to pupils"⁵. Finally, in education, "the hidden curriculum refers to the way in which cultural values and attitudes (such as obedience to authority, punctuality, and delayed gratification) are transmitted, through the structure of teaching and the organization of schools."⁶ There are numerous such messages conveyed indirectly. For example, that reading and mathematics are the most important elementary school subjects is clearly if implicitly communicated by scheduling more time for these subjects than for others, such as science and social studies, scheduling them in morning prime time rather than in the afternoon, and testing them more often than other subjects or skills. Thus, a major purpose of the hidden curriculum of public schools has been cultural transmission or teaching students the routines for getting along in school and the larger society. In other words, hidden curriculum usually serves to maintain the status quo, specifically the dominant culture and prevailing socioeconomic hierarchy. Hidden Curriculum appears in every school whether public or private, secondary school, high school or University. It is in the way we teach our students to become good citizens and follow the norms of society. Hidden curriculum is acknowledged as the socialization process of schooling. In some ways it can be argued that this so-called hidden curriculum is more important than the regular curriculum. Some will say that this hidden curriculum has not always been acknowledged. The norms of schools will prepare pupils to involve in the life of public sphere. These norms are for example independence, achievement, universalism, and specificity and that these norms are required to teach them in order to collaborate with modern industrial society.

A hidden curriculum is a side effect of an education, which are learned but not openly intended such as the transmission of norms, values, and beliefs conveyed in the classroom

38 and the social environment. Any learning experience may teach unintended lessons. Hidden curriculum

often refers to knowledge gained in primary and secondary school settings, usually with a negative connotation where the school strives for equal intellectual development (as a positive aim). In this sense, a hidden curriculum reinforces existing social inequalities by educating students according to their class and social status. The unequal distribution of cultural capital in a society mirrors a corresponding distribution of knowledge among its students. Early workers in the field of education were influenced by the notion that the preservation of the social privileges, interests, and knowledge of one group within the population was worth the exploitation of less powerful groups. Over time this theory has become less blatant, yet its underlying tones remain a contributing factor to the issue of the hidden curriculum. Several educational theories have been developed to help give meaning and structure to the hidden curriculum and to illustrate the role that schools play in socialization. Three of these theories, as cited by Henry Giroux and Anthony Penna, are a structural functional view of schooling, a phenomenological view related to the "new" sociology of education, and a radical critical view corresponding to the neo Marxist analysis of the theory and practice of education. The structural functional view focuses on how norms and values are conveyed within schools and how their necessities for the functioning of society become indisputably accepted. The phenomenological view suggests that meaning is created through situational encounters and interactions, and it implies that knowledge is somewhat objective. The radical critical view recognizes the relationship between economic and cultural reproduction and stresses the relationships among the theory, ideology, and social practice of learning. Although the first two theories have contributed to the analysis of the hidden curriculum, the radical critical view of schooling provides the most insight. Most importantly it acknowledges the perpetuated economic and social aspects of education that are clearly illustrated by the hidden curriculum.

Various aspects of learning contribute to the success of the hidden curriculum, including practices, procedures, rules, relationships, and structures. Many school specific sources, some of which may be included in these aspects of learning, give rise to important elements of the hidden curriculum. These sources may include, but are not limited to, the social structures of the classroom, the teacher's exercise of authority, rules governing the relationship between teachers and students, standard learning activities, the teacher's use of language, textbooks, audio visual aids, furnishings, architecture, disciplinary measures, timetables, tracking systems, and

39 curricular priorities. Variations among these sources promote the disparities found when comparing the hidden curricula corresponding to various class and social statuses.

Every school is both an expression of a political situation and a teacher of politics.

While the actual material that students absorb through the hidden curriculum is of utmost importance, the personnel who convey it elicit special investigation. This particularly applies to the social and moral lessons conveyed by the hidden curriculum, for the moral characteristics and ideologies of teachers and other authority figures are translated into their lessons, albeit not necessarily with intention. Yet these unintended learning experiences can result from interactions with not only instructors, but also with peers. Like interactions with authority figures, interactions amongst peers can promote moral and social ideals but also foster the exchange of information and are thus important sources of knowledge contributing to the success

of the hidden curriculum. Although the hidden curriculum conveys a great deal of knowledge to its students, the inequality promoted through its disparities among classes and social statuses often invoke a negative connotation.

For example, Pierre Bourdieu asserts that education related capital must be accessible to promote academic achievement.

The effectiveness of schools becomes limited when these forms of capital are unequally distributed. Since the hidden curriculum is considered to be a form of education related capital, it promotes this ineffectiveness of schools as a result of its unequal distribution. As a means of social control, the hidden curriculum promotes the acceptance of a social destiny without promoting rational and reflective consideration. According to Elizabeth Vallance, the functions of hidden curriculum include "the inculcation of values, political socialization, training in obedience and docility, the perpetuation of traditional class structure functions that may be characterized generally as social control." Hidden curriculum can also be associated with the reinforcement of social inequality, as evidenced by the development of different relationships to capital based on the types of work and work related activities assigned to students varying by social class. Although the hidden curriculum has negative connotations, it is not inherently negative, and the tacit factors that are involved can potentially exert a positive developmental force on students. Some educational approaches, such as democratic education, actively seek to minimize, make explicit, and/ or reorient the hidden curriculum in such a way that it has a positive developmental impact on students. Similarly, in the fields of environmental education and education for sustainable development, there has been some advocacy for making school environments more natural and sustainable, such that the tacit developmental forces

40 that these physical factors exert on students can become positive factors in their development as environmental citizens. While studies on the hidden curriculum mostly focus on fundamental primary and secondary education, higher education also feels the effects of this latent knowledge. For example, gender biases become present in specific fields of study? the quality of and experiences associated with prior education become more significant? and class, gender, and race become more evident at higher levels of education. One additional aspect of hidden curriculum that plays a major part in the development of students and their fates is tracking. This method of imposing educational and career paths upon students at young ages relies on various factors such as class and status to reinforce socioeconomic differences. Children tend to be placed on tracks guiding them towards socioeconomic occupations similar to that of their parents, without real considerations for their strengths and weaknesses. As students advance through the educational system, they follow along their tracks by completing the predetermined courses.

Hidden

curriculum refers to the unwritten, unofficial, and often unintended lessons, values, and perspectives that students learn in school. While the "formal" curriculum consists of the courses, lessons, and learning activities students participate in, as well as the knowledge and skills educators intentionally teach to students, the hidden curriculum consists of the

unspoken or implicit academic, social, and cultural messages that are communicated to students while they are in school.

The hidden curriculum concept is based on the recognition that students absorb lessons in school that may or may not be part of the formal course of study- for example, how they should interact with peers, teachers, and other adults? how they

should perceive different races, groups, or classes of people? or what ideas and behaviors are considered acceptable or unacceptable. The hidden curriculum is described as "hidden" because it is usually unacknowledged or unexamined by students, educators, and the wider community. And because the values and lessons reinforced by the hidden curriculum are often the accepted status quo, it may be assumed that these "hidden" practices and messages don't need to change- even if they are contributing to undesirable behaviors and results, whether it's bullying, conflicts, or low graduation and college enrolment rates, for example.

It should be noted that a hidden curriculum can reinforce the lessons of the formal curriculum, or it can contradict the formal curriculum, revealing hypocrisies or inconsistencies between a school's stated mission, values, and convictions and what students actually experience and learn while they are in school. For example, a school may publicly claim that it's committed to ensuring that all students succeed academically, but a review of its performance data may reveal significant racial or socioeconomic discrepancies when it

41 comes to test scores, graduation rates, and other measures of success. And because what is not taught in school can sometimes be as influential or formative as what is taught, the hidden curriculum also extends to subject areas, values, and messages that are omitted from the formal curriculum and ignored, overlooked, or disparaged by educators. While the hidden curriculum in any given school encompasses an enormous variety of potential intellectual, social, cultural, and environmental factors—far too many to extensively catalogue here—the following examples will help to illustrate the concept and how it might play out in schools:

Cultural expectations: The academic, social, and behavioural expectations established by schools and educators communicate messages to students. For example, one teacher may give tough assignments and expect all students to do well on those assignments, while another teacher may give comparatively easy assignments and habitually award all students passing grades even when their work quality is low. In the high expectations class, students may learn much more and experience a greater sense of accomplishment, whereas students in the low expectations class may do just enough work to get by and be comparatively uninterested in the lessons they are being taught. Similarly, schools may unconsciously hold students from different cultural backgrounds—for example, minorities, recently arrived immigrant students, or students with disabilities—to lower academic expectations, which may have unintended or negative effects on their academic achievement, educational aspirations, or feelings of self-worth.

Cultural values: The values promoted by schools, educators, and peer groups, such as cliques, may also convey hidden messages. For example, some schools may expect and reward conformity while punishing nonconformity, whereas other schools might celebrate and even encourage nonconformity. In one school, students may learn that behaviors such as following the rules, acting in expected ways, and not questioning adults are rewarded, while in other schools students learn that personal expression, taking initiative, or questioning authority are valued and rewarded behaviors. Similarly, if biased or prejudicial behaviors and statements are tolerated in a school, students may embrace the values that are accepted or modelled—either explicitly or implicitly—by adults and other students.

Cultural perspectives: How schools recognize, integrate, or honour diversity and multicultural perspectives may convey both intentional and unintended messages. For example, some schools may expect recently arrived immigrant students and their families to “assimilate” into American culture—for example, by requiring the students to speak English in school at all times or by not providing

42 translated informational materials or other specialized assistance. Other schools, however, may actively integrate or celebrate the multicultural diversity of the student body by inviting students and parents to share stories about their home country, for example, or by posting and publishing informational materials in multiple languages. Generally speaking, the concept of a hidden curriculum in schools has become more widely recognized, discussed, and addressed by school leaders and educators in recent decades. Ideas such as “white privilege, equity, and multicultural education to name just a few—have arguably led to greater tolerance, understanding, and even celebration of racial, cultural, physical, and cognitive differences in public schools. In addition, school communities, educators, and students are more likely than in past decades to actively and openly reflect on or question their own assumptions, biases, and tendencies, either individually or as a part of a formal school policy, program, or instructional activity. For example, topics such as bullying and diversity are now regularly discussed in public schools, and academic lessons, assignments, readings, and materials are now more likely to include multicultural perspectives, topics, and examples. Political and social pressures, including factors such as the increased scrutiny that has resulted from online media and social networking, may also contribute to greater awareness of unintended lessons and messages in schools. There are, therefore, a host of obligations that the child is required to shoulder. Together they constitute the discipline of the school. It is through the practice of school discipline that we can inculcate the spirit of discipline in the child”. The hidden curriculum as a socialization of schooling can be identified by the social interactions within an environment. Thus, it is in process at all times, and serves to transmit tacit messages to students about values, attitudes and principles. Hidden curriculum can reveal through an evaluation of the environment and the unexpected, unintentional interactions between teachers and students which revealed critical pedagogy.

Also, many of them claim that the demands of upper and middle class are dominant throughout schooling. Particularly, the concept of hegemony and resistance are significant in the evaluation of hidden curriculum. 1.6

Curriculum Planning, Implementation and Evaluation. Role of Special Teachers of the Visually Impaired 1.6.1 Curriculum

Planning

Curriculum planning is the decision- making process about the content and the

43 organization of learning for which the school is responsible. Different groups of people decide on the variety of topics and issues concerned with the educational needs of pupils.

Building an effective Curriculum is a process developed to help schools and centres review and revise their curriculum structures. Involving the school community Building curriculum is a collaborative process which can be used to involve and engage pupils, parents and other partners. Identifying your priorities for change Staff need to identify and examine together the challenges and opportunities posed by their own school or centre. Tools to support you in reviewing your curriculum structure, including a strategic curriculum planner. A resource to help primary schools evaluate and develop different aspects of their curriculum. A clear and concise 'toolkit' to help secondary schools evaluate their curriculum across the broad general education. Talking Heads implementing Curriculum for Excellence in the senior phase seven head teachers talk about building and developing the curriculum in secondary schools, while parents discuss how the results would affect their children. Putting the learner at the centre through consulting pupils on how learning should be planned. Schools share 'works in progress' illustrating how they are focusing on particular aspects of their curriculum design. The final step in the building curriculum process is to create own curriculum plan. An outline of the framework's role as a technical document for curriculum planners. This template can be used to bring structure to curriculum planning. Materials to help schools and centres agree next steps as they begin to construct a strategic curriculum plan. Involving the school community identifying your priorities for change sharing practice curriculum planning. Religious observance is an essential part of the totality of the learning experience for every young person and supports whole school planning. Good curriculum planning in schools often requires overcoming many obstacles. With very few exceptions, even small scale curriculum planning requires that participants engage in extensive deliberations. Therefore, finding appropriate times for participants to meet is often crucial to the success of a project. Another difficulty is that participants may not be aware that curriculum planning rarely proceeds smoothly along the lines originally envisaged for it, arriving at the one inevitable proposal for curriculum change. In the process of curriculum planning, new ideas surface and new directions are explored. How a planned curriculum is implemented as the enacted curriculum in any school is a complex process that can vary enormously from school to school. The personnel of some schools may prefer to make few changes in the original plan (as in fidelity of use),

44 the personnel of other schools may choose to make many changes (as in mutual adaptation), or -as is often the case there may be considerable differences of opinion among the personnel of any school. The only certainty about curriculum implementation is that there is no one right way of going about it for all teachers in all schools. Curriculum planning can be done through three levels. These are as follows: the planning of policies, the planning of programs, and the planning of lessons. We will focus on how planning by teachers actually proceeds in individual schools, and in so doing, we examine in detail the contributions made to curriculum planning by people often referred to as "key stakeholders." Key stakeholders include teachers, principals, parents, students and external facilitators all the people who for personal or professional reasons ordinarily have the strongest interests in planning. Either their lives are touched directly by the curriculum (as in the case of teachers, parents, and students), or their professional roles include some direct responsibility for the curriculum (as in the case of teachers, principals, and external facilitators). We will look at what happens when a planned or written curriculum is enacted in a classroom. We will consider why the enacted curriculum may differ considerably from the planned curriculum and under what circumstances the differences that occur are desirable or undesirable. In addition we will critically review recent thinking on the process of curriculum implementation, describing both strategies and tactics that seem to work well and what about the process of implementation remains problematic and puzzling to researchers. Ø Objectives: To differentiate among three levels at which curriculum planning occurs in schools: policy, programs and lessons. To reflect on the backgrounds, priorities, and skills ordinarily brought to curriculum planning by key stakeholders, especially teachers, principals, parents, students and external facilitators. To become familiar with the major problems involved in curriculum implementation. To understand the implications of the ideas of fidelity of curriculum implementation and adaptation in curriculum implementation. To critically reflect on the basic ideas that underlies research on curriculum implementation. To critically reflect on some common approaches that has been used in schools to support the process of curriculum implementation. The various players in the curriculum process are teachers, principals, parents, students and external facilitators as you look at the list of players in the curriculum process, you probably identify with many of these

45 roles. You wear many different hats in your professional lives. You are all students. Some of you have administrative duties while others of you will play that role sometime in the future. Many of you are parents. All of you are teachers. Some of you have worked as a consultant or have functioned as an external facilitator for a period of time in one educational setting or another. If there are any of these hats you have not worn, you are well acquainted with people who do wear those hats. Ø Problem to Solve: Marsh and Willis identify three levels of curriculum planning: the planning of policies, the planning of programs, and the planning of lessons. They also point out the role "key stakeholders" such as students, teachers, parents, principals and external facilitators play in the process of curriculum planning. The member of a curriculum planning/problem solving group two distinguished external facilitators have agreed to work with you in small groups. Each facilitator has a pressing problem your group needs to help solve. Elementary School who are wrestling with the challenges of program accountability as Teachers in Need of Assistance (TINA). Ø Curriculum Process: Each external facilitator will "call" their respective group together by posting an initial message to the group. Email addresses are listed on the committee roster above. This initial posting should establish the setting for the problem. Each committee member should respond to their committee's curriculum problem from the perspective of their assigned role. Each committee member must weigh in on questions related to their issue as found on the description linked as well as any additional information provided by the curriculum facilitator. The deliberation activity of the committee will constitute the group discussion for the week minimum of three postings. By the end of the week each facilitator will post to the listserv the recommendations of their Curriculum Planning/Problem Solving Committee. These will be available for review by both curriculum groups. Any member of either curriculum group will then be welcome to comment on the outcome of each committee's curriculum work.

1.6.2 Implementation After the preparation of learning materials or activities which all come under curriculum, the next step is the implementation of curriculum in the classroom. This is the stage of 46 actual teaching- learning or transaction of curriculum. Teachers, principals, supervisors and members of school management are given training in the proper implementation of curriculum. The following factors leading to the efficient implementation of the curriculum: ●●●● Adequate preparation of the teachers by the boards and State Departments of Education for meeting the changed requirements of the new curriculum. ●●●● Sufficient supply of the teaching aids and equipment needed for the implementation of the curriculum. ●●●● Receptivity of the community to the new curriculum ●●●● Adequate preparedness of the students to accept the new curriculum with its additional requirements of energy, money and time ●●●● Adequate supervisory and guidance facilities for teachers needed for effective implementation of the curriculum. The term "implementation" includes to activities, the first that relates to preparatory activities that need to be completed once curriculum has been developed and made public. The second relates to transaction .Implementation is that which works to relate the identification of those activities that need to be completed well before transaction this activities can be three categories: 1. Activities to be completed before implementation 2. Activities to be completed during implementation 3. Activities to be completed after implementation The first to activities listed above are important as they influence curriculum transaction. The last one is important as it is key to curriculum review and revision. Thus a provision needs to be provided in curriculum planning that after development of curriculum, a comprehensive road map will be developed to ensure that all necessary preparatory activities are pre-planned. By way of illustration listed below some activities that must be completed before and after implementation face.

47 Road map for curriculum implementation 1.6.3 Evaluation In relation to curriculum, evaluation is the process of making value judgements about the merit or worth of a part or the whole of a curriculum.

The nature of a curriculum evaluation often depends on its audience and purpose. The potential audiences include: Policy makers and other stakeholders (administrators, teachers, students, parents, communities) - to inform future action. (Donors - to attract funding or to report on the utilization of funds. Researchers - for international comparison and identification of effective practices.) Evaluation of curricula is typically concerned with the: Impact of 48 the curriculum: on individual students, their needs, their level of engagement and their performance? On society, including the appropriateness of values communicated and attitudes fostered, and the level of public satisfaction? on the economy including labour markets as an indicator of economic development? Process through which the curriculum was developed? Content and design of the curriculum compared with: recent social, technological, economic or scientific changes? Recent advances in educational research and educational paradigms? Possible future directions for curriculum change. So it may be say that curriculum evaluation refers to evaluation of the different components of curriculum.

Meaning

of Curriculum Evaluation essentially is the provision of information for the sake of facilitating decision making at various stages of curriculum development. This information may pertain to the program as a complete entity or only to some of its components. Evaluation also implies the selection of criteria, collection and analysis of data. It includes obtaining information for use in judging the worth of a programme and procedure. It is a comprehensive term and transcends standardized tests covering all means of ascertaining the results of construction. Evaluation of curriculum is an integral and essential part of the whole process of curriculum development. It is a continuous activity and not a "tail- end-process". Evaluation and planning are complementary processes which occur almost simultaneously and continuously. Planning is made on the basis of evaluation and vice versa. However, as a separate state evaluation has its own entity.

The importance of curriculum evaluation is to determine the value of the curriculum itself is the curriculum appropriate for the particular group of students with whom it is being used? Are the instructional methods selected, the best choices in the light of the objectives sought? Is the content the best that could be selected? Are the materials recommended for instructional purpose appropriate and the best available for the purpose envisaged? ●●●●

Objectives of Curriculum Evaluation

1. To determine the outcomes of a programme. 2. To help in deciding whether to accept or reject a programme. 3. To ascertain the need for the revision of the course content.

4. To help in future development of the curriculum material for continuous improvement. 5. To improve methods of teaching and instructional techniques. ●●●●

Types of Curriculum Evaluation

According to Scriven, following are the 3 main types

1. Formative Evaluation. It occurs during the course of curriculum development. Its purpose is to contribute to the improvement of the educational programme. The merits of a programme are evaluated during the process of its development. The evaluation results provide information to the programme developers and enable them to correct flaws detected in the programme. 2. Summative Evaluation. In summative evaluation, the final effects of a curriculum are evaluated on the basis of its stated objectives. It takes place after the curriculum has been fully developed and put into operations. 3. Diagnostic Evaluation. Diagnostic evaluation is directed towards two purposes either

for

placement of students properly at the outset of an instructional level (such as secondary school), or to discover the underlying cause of deviancies in student learning in any field of study. 1.6.4

Role of

Special Teachers of the Visually Impaired

A Teacher of Students with Visual Impairments (also called a Teacher of the Visually Impaired, a vision specialist, VI teacher, vision itinerant teacher, etc.) is typically a licensed special education teacher who has received certification and specialized training, in meeting the educational needs of students who are blind or have visual impairments ages birth through 21 (states vary on the criteria for certification as a Teacher of Students with Visual Impairments). This is an instructional position, as opposed to a related service or vision therapy.

The role of the Teacher of Students with Visual Impairments (TVI)

is to provide direct and/or consultative special education services specific to vision loss. The TVI provides support to students, teachers, and parents and acts as a liaison with community services. The TVI works with the educational team by advising the team about ways of enhancing the student's learning by adapting activities and materials to the student's abilities.

Although the TVI is not an academic tutor, they may spend some time ensuring that the student understands concepts introduced in academic

courses. The TVI may help choose appropriate educational materials, and may brainstorm with teachers and therapists about effective adaptations. By working together, classroom teachers, therapists, and the TVI can create a classroom environment that encourages independence, academic success, and prepare the student to be the most productive member of society they can be.

The teacher of students with visual impairments

is the central figure on the educational team for a visual impairment. This is the professional who has expertise in how visual impairment affect child's development and learning, as well as the strategies and tools that can help child learn about the world, perform everyday activities, and participate in the general curriculum and other activities in school. Therefore, child is likely to be working with the teacher of students with visual impairments on a day to day basis. He or she will probably serve as the coordinator of the educational team and as a resource for the other team members, including their parents. It may sometimes hear this teacher referred to as a "vision teacher" or by the abbreviation "TVI." The specific responsibilities of the teacher of students with visual impairments may vary, depending on child's age and needs, the goals his educational team sets for him, the type of educational program child participates in, and the policies of the particular school district. The role of the teacher of students with visual impairment may include some or all the following: teaching the specific skills that child needs to learn because of his visual impairment. Generally these are adapted ways of doing everyday activities and methods of participating in the school curriculum, such as reading and writing in braille, using a low vision device, or independent living skills. These skills are often known as the expanded core curriculum.

Conducting various assessments of the child to determine his abilities and needs working with other family members in various ways, such as helping to learn skills which need to teach such as helping them to learn skills that need to teach the child or suggesting ways to arrange their home or do household chores that will make it easier for the child to participate in family life making referrals for additional services which child may need, such as for orientation and mobility (O&M) instruction or a clinical low vision evaluation from a low vision specialist meeting with family members, the child's regular education teacher, and other members of the educational team to discuss his progress and make suggestions for strategies to make his school work accessible and to include him to the greatest extent possible in all school, classroom, and extracurricular activities

preparing or obtaining learning materials, textbooks, and examinations in the appropriate accessible format for the child (such as braille, large print, audio, or electronic format) analysing the classroom and other environments for access and safety related to a student's

51 visual impairment or blindness, and advising other members of the team about how best to organize the classroom and materials providing consultation and training for teachers, Para educators, and other school personnel on effective strategies for teaching students with visual impairments directing the Para educator, if one has been assigned to the child or his class, in providing support to the child. Teachers of students with visual impairments often work as "itinerant" teachers, which mean that they travel from school to school within a particular area or school district to work with the students to whom they've been assigned. At the school, there are different ways in which the teacher of students with visual impairments might work with the child.

For example, they may work together in the child's regular classroom to help with the on-going lesson, in an empty classroom, or in a designated resource room, alone or with a group of students. The teacher of students with visual impairments might also meet with the child before or after school. Or, he or she might only observe the child occasionally in order to consult with the regular education teacher about your child's progress. How often they meet depends on the services designated by your child's Individualized Education Program (IEP) (or Individualized Family Service Plan (IFSP) if he is younger than 3 years old). Because the teacher of students with visual impairments has an on-going role with a child in teaching the expanded core curriculum, it's important to understand that he or she is not responsible for teaching the general education curriculum that all students learn in school. That role belongs to the classroom teacher. The responsibilities of the classroom teacher with regard to the child might be summarized as follows: teaching academic and social curricula, assigning grades, and maintaining discipline for all students in the class, including the child who is visually impaired providing textbooks and instructional materials to the teacher of visually impaired students in a timely manner so that the material can be prepared in alternate formats that the child needs communicating and meeting regularly with the teacher of visually impaired students to discuss the child's progress and plans for meeting his future educational and social needs creating a classroom climate that is comfortable for all students The teacher of students with visual impairments' contribution to the general education classroom is to consult with the classroom teacher on ways of making the general curriculum accessible to the child be responsible for preparing classroom materials in formats that are accessible to the child. The teacher of students with visual impairments

may also teach some of the concepts that the child needs to learn in preparation for a particular lesson. For example, to prepare the child for a science lesson about eclipses, the teacher of students with visual impairments may use hands on materials to teach concepts about

52 the sun, moon, and earth and the rotation and revolution of the planets that might be taught to the rest of the class using pictures. Since

both the teacher of students with visual impairments and the

regular classroom teacher play such a central role in your child's education, it's important for these two professionals to remain in close contact about the best ways of meeting child's needs.

The Teacher of Students with Visual Impairments (TVI) has the following roles and responsibilities: ●●●● Has primary responsibility for specialized instruction and services required meeting the unique educational needs of her visually impaired students? ●●●●

Possesses the skills and abilities necessary to provide and coordinate this specialized instruction. ●●●● Assists the student, parents, special and regular education personnel, and the student's sighted peers in understanding the unique educational needs and learning characteristics of visually impaired students, becoming aware of services and support available from local programs for

visually impaired students, acquiring

information regarding local, state, and national resources

for the education of

visually impaired students, and interpreting the visually impaired

student's specific eye condition, the educational implications of the visual impairment, and the results of functional vision and learning media assessments. ●●●●

Consults regularly with the classroom teacher, other regular and special education personnel, parents, and others to coordinate programs and services for

the visually impaired student. ●●●●

Assists the site administrator and teachers in making environmental adjustments for the student in the school. ●●●●

Shares responsibility

with classroom teachers in the identification of instructional areas in which the student requires assistance. ●●●●

Assures that large-type or braille texts, supplementary materials, educational aids, and equipment needed by the visually impaired student, and the classroom teacher, are provided in a timely manner

to ensure the student's maximum participation in all classroom activities (appropriate educational materials may be prepared or adapted by the VI teacher, or they may be obtained from educational, clerical, or transcribe services.)

53 ●●●●

Provides instruction

in the development and maintenance of skills to meet the student's unique educational needs in the following areas, as indicated in the IEP: ✓✓✓✓✓ low vision & visual efficiency skills, ✓✓✓✓✓ concept development & academic skills,

✓✓✓✓✓

daily living skills, ✓✓✓✓✓ career & vocational education skills, ✓✓✓✓✓ communication skills (these skills include braille reading and writing as appropriate), ✓✓✓✓✓ Social/emotional skills and abilities, & sensory motor skills. ✓✓✓✓✓

Prepares

sequential and meaningful instruction geared to the student's assessed needs, IEP goals and objectives, functioning, and motivational

levels. This instruction should be reflected in

weekly or monthly lesson plans, as appropriate. ✓✓✓✓✓

Provides assistance to

the classroom teacher in academic subjects and activities of the classroom that, as a direct result of the student's visual impairment, require adaptation for the student. ●●●●

Provides initial and on-going assessment: consults with assessment team to determine appropriate testing materials and modifications needed, assists with assessments when needed, interprets assessment results when needed. ●●●●

Conducts functional vision/learning media assessments and produces written reports. ●●●● Attends ARD and IEP meetings for students with visual impairments. ●●●●

Schedules time efficiently for assessment, instruction, planning, preparation of materials, travel, and conferences with relevant school and other key individuals. ●●●●

Maintains on-going

contact with parents to assist them in the development of a realistic understanding of their child's abilities, progress, and future goals. ●●●● Provides in-service training programs for school personnel and students and education for parents regarding the needs of visually impaired students

and adaptations, programs, and services for these students. ●●●● Makes available

pamphlets, films, and other public information materials that may be useful in developing realistic and unprejudiced attitudes toward

visually impaired students.

54 ●●●● Coordinates

with

other personnel, such as transcribers, readers, counsellors, O&M specialists, career/vocational education staff, and rehabilitation

counsellors. ●●●● Maintains a

current reference library of professional materials and resources. ●●●● Acquires information and training about current research, development, and technology. ●●●●

The Classroom Teacher (regular, special class, or resource specialist has the following roles and responsibilities: ●●●●

Provides instruction

in appropriate academic and non-academic content areas to the visually impaired student in the classroom. ●●●●

Works cooperatively with the teacher of students with visual impairments to identify the student's areas of educational need, including unique education needs, coordinate instruction and services to meet these needs,

provide, in a timely manner,

classroom materials that need to be reproduced in another medium, determine mutually convenient times during the school day for scheduling

the teacher of students with visual impairments to work with the student,

modify classroom procedures and environment to meet the specific needs of the visually impaired student for

participation in classroom activities,

and exchange information concerning the visually impaired student with parents and other individuals on a regular basis.

The Orientation and Mobility Specialist has the following roles and responsibilities ●●●● Instructs the visually impaired student

in the development of skills and knowledge that enables him or her to travel independently,

based on assessed needs and ability. ●●●● Teaches the visually impaired student

to travel with proficiency, safety, and confidence in familiar and unfamiliar environments. ●●●●

Consults regularly with

sighted peers, parents,

classroom teachers, physical education teachers, and/or other special education personnel to assist in home and classroom environmental modifications, adaptations, and considerations and to ensure reinforcement of appropriate

O&M skills that will encourage the visually impaired student to travel independently in these settings. ●●●● Works with the teacher of students with visual impairments to conduct the functional vision assessment as it relates to independent

travel. ●●●●

Conducts assessments that focus on both long and short-term needs of the student.

55 ●●●● Includes in the assessment report the needs and strengths of the student and an estimate of the length and frequency of service necessary to meet identified needs. ●●●● Prepares

sequential and meaningful instruction geared to the student's assessed needs, IEP goals and objectives, functioning, and motivational

levels. This instruction should be reflected in

weekly or monthly lesson plans, as appropriate. ●●●●

Prepares

and uses equipment and materials, for example, tactile maps, models, distance low vision devices, and long canes,

for the development of

O&M skills. ●●●● Transports the student with parent permission

to various community locations, as necessary, to provide meaningful instruction in realistic learning environments. ●●●● Is responsible for

the student's safety

at all times and in all teaching environments while fostering maximum independence. ●●●●

Evaluates the student's progress on an ongoing basis with progress reports each 6/9 weeks as required. ●●●●

Keeps progress notes on each student. ●●●● Participates in necessary parent conferences and meetings. ●●●● Provides in-service training to regular and special education personnel, sighted peers, and parents concerning the O&M needs of the student and appropriate methods and procedures for interacting with the visually impaired person that will foster maximum independence and safety. ●●●●

Provide O&M instruction, where appropriate, in a number of specific

areas: ✓✓✓✓ body imagery, ✓✓✓✓ laterality, ✓✓✓✓ environmental concepts, ✓✓✓✓ gross and fine motor skills related to independent travel, ✓✓✓✓ sensory awareness, stimulation, and training, ✓✓✓✓ spatial concepts, ✓✓✓✓ compass direction concepts, ✓✓✓✓

sighted guide procedures ✓✓✓✓ basic protective and information-gathering techniques

56 ✓✓✓✓

orientation skills ✓✓✓✓ map skills ✓✓✓✓ cane skills, ✓✓✓✓ use of residual vision ✓✓✓✓ low vision devices related to travel skills ✓✓✓✓

urban, suburban, and rural travel, ✓✓✓✓ travel in business districts, ✓✓✓✓ procedures for crossing streets including how to deal with traffic control signals, ✓✓✓✓ use

of public transportation systems, ✓✓✓✓ procedures for use of the telephone for information gathering and for emergencies, ✓✓✓✓

procedures

for interacting with the public ✓✓✓✓ knowledge and application of community address systems, ✓✓✓✓ procedures for travel and independent functioning in places of public accommodation, ✓✓✓✓ skills of daily living, ✓✓✓✓ sensory/motor skills in coordination with the physical or occupational therapist and teacher of ✓✓✓✓ students with visual impairments,

and ✓✓✓✓ Skills for independent living.

What to expect from the Teacher of Students with Visual Impairments: ●●●● Interpret Medical Reports As part of determining a student's eligibility and the impact of the visual impairment, the Teacher of Students with Visual Impairments will need to have the skills and training to read and interpret medical eye reports. The TVI will determine the implication thereof for educational and home environments. ●●●● Conduct Specialized Assessments and Make Recommendations The TVI will conduct Functional Vision Assessments to determine how much usable vision a student has to perform visual tasks. This assessment is initially conducted to

57 determine the need for services from a teacher of students with visual impairments and to determine appropriate goals and level of support needed. This evaluation is updated at a minimum, every three years to determine on-going eligibility and need for school based vision services. The TVI may also recommend appropriate specialized evaluations as needed, particularly in low vision, orientation and mobility, and adaptive physical education. This evaluation is conducted even if the student has no usable vision. ●●●● Actively Participate in the Individualized Education Program (IEP) The TVI will need to communicate with the team members on how the student's performance may affect their school performance by providing information on the student's

learning style, utilization of visual information, and other strengths unique to individual

students who are visually impaired. The TVI will identify any

goals and objectives in specialized areas related to the visual needs of the student.

The TVI will also

identify instructional methods and materials for meeting goals and objectives.

Finally, the TVI will recommend appropriate service delivery options, including class placement, physical education, related services,

specialized equipment (/assistive- technology.html),

adaptations in testing procedures, and time frames for implementation. Consideration will be taken as to the current and future reading and writing media for the student with a visual impairment based on reading distance, reading rates and accuracy, portability of reading skills, visual fatigue, and tactual sensitivity. •••• Recommend Educational & Instructional Strategies The TVI will assist in determining and procuring classroom equipment and materials necessary for the student with visual impairments to learn (braille, low vision devices, assistive technology, computer) including ensuring necessary room modifications and lighting changes. The TVI will provide the classroom teacher with information regarding the specialized strategies needed to teach a student who is blind or visually impaired. The TVI will also assist in obtaining specialized materials, including procuring materials from the American Printing House for the Blind (APH), providing braille, recorded/ enlarged materials, and other needed materials. •••• On-going Observations The TVI conducts on-going observations of the student in a variety of familiar situations performing routine tasks or activities to assess how the student is using their vision. In doing this, the TVI can and out what motivates the student to look. The TVI will then use objects and activities similar to those that have been motivating in the past. It is also

58 beneficial to get an understanding of how the student spends their time. What does the student do? How does the student play and with what? Where do they go? Who do they play or interact with? This is a process to identify the student's existing (and desired) activity setting. These observations will assist the TVI in ensuring the goals and accommodations as well as level of service

in ensuring the goals and accommodations as well as level of service continue to be appropriate. •••• Use of Natural Environments to Address Goals

Teaching techniques to enhance vision should not be taught in isolation. It is important to look at what the needs and activities of the student are in school and in their everyday life that are a?acted

by their visual performance, and teach to those tasks. If the family/ teachers are interested in obtaining other objects for the student to play with, then the TVI can assist the family and/or teacher in obtaining such items. The responsibility of the TVI is to support the student with what he/she has everyday access to, where he/she is, and sharing information that matches the student's/families/classroom priorities (watching television, playing on the computer, playing with toys or games). These activities provide multiple learning opportunities. It is easy to take in a bag of toys, but more challenging and appropriate to explore existing toys that the student will have daily access to, for continued exposure/practice.

Learning takes place at all times, so it is best to use what is available/accessible to give the student more practice in using existing skills and developing new abilities. "Toy bag treatment sessions" typically do not promote functional skill use and learning in natural settings. Some skills are best addressed outside of the regular classroom to avoid visual and auditory distractions. The goal should be to learn the skills and then begin to transfer those skills during classroom activities. ••••

Communication with Caregivers and Classroom Teachers The TVI will want to have on-going communication with the caregivers and classroom teachers in order to try to develop a better understanding of the student. An itinerant teacher will not have the same rapport with the student as they do not spend as much time with them. For that reason, it is helpful to talk with parents and classroom teachers who do have this rapport about how they feel the student is doing, if they are addressing the goals and how the student is functioning. The TVI may ask to observe the teacher working with the student to observe how the student is functioning within the normal routine and with familiar adults. •••• Direct Instruction in the Expanded Core Curriculum

59 The TVI will determine which areas of the Expanded Core Curriculum (ECC), a unique curriculum that addresses needs a student who is blind or visually impaired may have that are not addressed within the standard curriculum.

Although not all students will have needs in all areas of the ECC, the areas of the ECC include: Compensatory, Functional and Communication Skills; Sensory Efficiency; Orientation & Mobility; Social; Independent Living; Recreation & Leisure; Use of Technology; Career & vocational; and Self Determination. 1.7

Core Curriculum and Expanded Core Curriculum- Meaning, Need and Components 1.7.1
meaning

of core curriculum: The core curriculum relies on structuring. It attempts to develop integration to serve the needs of students and to promote active learning and significant relationship between life and learning. Organization of curriculum is based on different point of views. Many educationist have considered the curriculum and its content in different manner, some considered psychological aspects and others have taken philosophical dimensions. There can be some components which may be included and there are others which need not be included in the curriculum. A student can choose the components as per their requirements. Still there are some components which are essential for every student irrespective of their specific requirements. These essential components are termed as core curriculum. Educators define 'core curriculum' as knowledge and skills expected to be learned by a student by high school graduation.

Generally, the core curriculum consists of knowledge and skills related to academic subjects. Mastery of the core curriculum is

what both parents and teachers stress as essential for academic demands of the core curriculum. 1.7.2 need of core curriculum: Generally many words like fixed, essential, centered etc. are being used synonymously for core which means compulsory. The term 'core' refers to the educational concept, which was used in 1940's for the first time. The intention of this concept is to make the component of curriculum more meaningful to all students. According to Oliver 1965, the core concept has two basic components: time and philosophy. Time is usually

60 administered through a block time concept. For example, two or more concepts are joined together in order to study a wide range of related topics. Whereas the philosophy of 'core' involves the breaking down the strict boundaries between two difference concepts. Manning and Oliver have mentioned that students may study a topic from literacy, historical, mathematical, educational, sociological, psychological and artistic, viewpoints concurrently rather than study them in an isolated manner. But according to Dewey's philosophy of experimentalism is the basis for the core curriculum. Dewey viewed learning as continuous reconstruction of experiences and problem solving as an important part of learning. Cultural facts have contribution towards the nature of core proposals. On the other hand according to cognitive theories of learning dynamic and organic process are the components of core curriculum. The core curriculum's primary focus is on academic content. In any educational setup the core curriculum is deemed central and usually mandatory for all students of a school

system. According to the report on the core curriculum the core curriculum referred to intellectual experiences and skills that are required for all students. Educationists have defined core curriculum as curriculum is which a few subjects are essential and others are elective. The core subjects have to be studied by each student whereas elective subjects can be opted on the basis of individual interest and abilities through which child can get the experiences of the problems related to self and society and thus to improve his future life. The main purpose of core curriculum is to develop a human being and human society as well. So the needs of core curriculum are as follows- ●●●● Learning experience and process from the backbone of core, not mastery of factual knowledge subject serves as a mean or tool for engaging common social and personal needs, not as an end in itself. ●●●● Core curriculum emphasizes problem solving by the group across fields and discipline textbooks and teachers do not control the agenda. ●●●● More time is required for core curriculum than the standard framework. ●●●● Core curriculum becomes the organizing scheme for the entire school experiences, non core curriculum are activities, supplement core curriculum activities. ●●●● Teachers guide students inside and outside the classroom, option, working with the same pupils for few years.

61 ●●●● The basic needs and learning experiences of student take precedence over subject matter. The basic needs can be addressed in various manners. The learning experiences must engage the students to move forward towards freedom held out by liberal education. ●●●● The contents in core curriculum integrated through various disciplines, themes, content, skills, ways of knowing, modes of teaching-learning process and combination of all these. In other words, integration in core curriculum is basically a cross-disciplinary approach. ●●●● The contents of core curriculum emphasis on problem solving and discussion. In core curriculum teacher act as integrators, agenda, settlers, modules of interpretive discovers, partners in conversation and mentors rather than as authoritative distributors of knowledge. ●●●● In core curriculum learning is not restricted to the walls of classrooms. Most of the components of core curriculum include the informal activities outside the classroom. For example common meals at mess, lectures, films, field trips, etc. in core curriculum one to one instruction is possible even out- side of the classroom. ●●●● In core curriculum the contents can be provided to the students through original to be the students through original materials like film, art, music, drama, or any other original source it is not necessary to use book in curriculum transaction through core curriculum. ●●●● Subject matter is considered as crucial as they are applied to original sources core curriculum is also able to pressure or interpret the knowledge. ●●●● The contents of core curriculum have a common benefit of the students. It is the most essential characteristic of which state its essentiality to all beneficiaries. The core curriculum also involves a special programme for faculty development. ●●●● Core curriculum is flexible in nature. There is provision of including the specific needs and interest of the students. ●●●● All activities of core curriculum is designed and prepared by the collective efforts of teacher and the students as well. It is common belief that through such step the students can be well versed with every step of core curriculum. A teacher can play a crucial role as a specialist and leader of a group.

62 ●●●● The areas of core curriculum are essential for all students. Core curriculum is designed through equal experiences. It is believed about these experiences that these are essential for every segment of society and its members irrespective of their ability, social status and vocational plans. 1.7.3 Components of Core Curriculum Components of core curriculum depend on various objectives. These are as follows- ●●●● Critical Thinking Skills - to include creative thinking, innovation, inquiry, and analysis, evaluation and synthesis of information. ●●●● Communication Skills - to include effective development, interpretation and expression of ideas through written, oral and visual communication. ●●●● Empirical and Quantitative Skills - to include the manipulation and analysis of numerical data or observable facts resulting in informed conclusions ●●●● Teamwork - to include the ability to consider different points of view and to work effectively with others to support a shared purpose or goal ●●●● Personal Responsibility - to include the ability to connect choices, actions and consequences to ethical decision-making ●●●● Social Responsibility: to include intercultural competence, knowledge of civic responsibility, and the ability to engage effectively in regional, national, and global communities

By the use of these objectives the core curriculum follows various components, which are very helpful for making a person being a human. Here the components of core curriculum are discuss underline- 1. Communication Courses in this category help in understanding, and building the skills needed to communicate persuasively. Course involve the command of oral, aural, written, and visual literacy skills that enable people to exchange messages appropriate to the subject, occasion, and audience
Fundamental to academic and professional success is the ability to communicate ideas clearly, accurately, and in an engaging way. The Core writing component enhances students' capacity to organize, to analyse, to interpret, and to argue persuasively and ethically. The writing component enables students to produce work of increasing complexity for multiple audiences.

Courses included in the communication component of the core curriculum are designed to enable the student to communicate 63 effectively in a style appropriate to the subject, occasion, and audience.
Courses listed in this area of the core must be designed to help students develop the Student Competencies listed below. Student Competencies 1. To understand and demonstrate effective written, oral and visual communication processes through invention, organization, drafting, revision, editing, and presentation. 2. To

choose a method of communication appropriate to a specified purpose and audience. 3. To weigh alternative viewpoints and work collaboratively with others in producing or analysing effective communication messages. 4. To organize ideas logically around a central theme in paragraphs, sections, and entire works using appropriate grammar, syntax, punctuation, and spelling. 5. To develop claims or hypotheses through analysis, drawing appropriate conclusions, and using well-reasoned arguments and supporting evidence while identifying logical flaws and fallacies and weighing alternative viewpoints. 6. To describe the ethical consequences and implications of one's messages on audiences. 7. Students will be able to think, read, and write analytically, critically, and creatively. 8. They will be able to express ideas coherently, to work with a variety of research methods, and to construct effective arguments using appropriate evidence.

2. Language, Philosophy

and Culture - Courses in this category focus on how ideas, values, beliefs, and other aspects of culture express and affect human experience. Courses involve the exploration of ideas that foster aesthetic and intellectual creation in order to understand the human condition across cultures 2.1

Modern and Classical Languages The Modern and Classical Language component provides students with a level of proficiency in a second language sufficient to insure successful communication in the cultural environment of the chosen language. Integral to the acquisition of communicative competency is the development of cultural sensitivity to different patterns of thought

64 and values. Study of a second language enhances analytical skills, broadens one's vision of the global dimensions of knowledge, and helps foster respect for the value and diversity of human life. The language component can enhance the major field of study and cross disciplinary inquiry by providing access to information and ideas otherwise unavailable.

Student Competencies 1. Students choosing a modern language will demonstrate the ability to handle communicative tasks and to express personal meaning in the second language at a level equivalent to "Intermediate" as described in the language proficiency guidelines of the Council of Teachers of Foreign Language. 2. Students will also show an understanding and an awareness of cultural differences. Students opting for a classical language will demonstrate an ability to understand texts of intermediate difficulty in the chosen language. 2.2 Philosophy A key element in Catholic and Jesuit education, philosophy provides a rational and critical way of examining fundamental, enduring questions about the human condition. These questions include the relationship of self and society and the foundations of sciences, aesthetics, and religion, especially the existence and nature of the divine. Philosophy assists students to examine critically their ethical convictions by exploring the best rational justifications for ethics given in Western philosophy. Thus, Core philosophy courses prepare students to approach critically and rationally the problems of the self, society, God, and ethical life. Student Competencies 1. Students will acquire a basic understanding of some of the foundational texts in philosophical thought. 2. They should be able to think independently and creatively about questions relating to humanity, to evaluate and to formulate philosophical arguments, and to understand the possible rational justifications for their beliefs. 2.3

Cultural Diversity The Core Curriculum Cultural Diversity component is addressed by two courses: one in "Cultural Diversity in the country" and one in "Global Citizenship." For the Purpose and Student Outcomes of each of these courses, please consult the following :

65 1.

Theological Studies Growth in theological understanding is rooted in the mission of Saint Louis University as a Catholic, Jesuit institution. The Theological Studies component promotes this growth in three phases: (

a) Discovery: Students are introduced to the Hebrew and Christian scriptures from historical and literary perspectives, to fundamental theological concepts, and to the early history of Christianity. (b) Insight: Phase 2 focuses on comparative theology (the search for truth and meaning in the major world religions) and broadens understanding of universal as well as specific theological concepts. (

c) Integration: Students learn to apply essential religious and theological insights to specific social and cultural contexts, moral choices, professional and personal lifestyles, and global realities.

Courses included in the humanities component of the core curriculum are designed to expand students' knowledge and understanding of the human condition and human cultures through the critical study of works of human imagination and thought. Courses listed in this area of the core must be designed to help students develop the following Student Competencies. Student Competencies 1. To critically analyse and interpret works and their impact on human life and society in a discipline such as literature. 2. To articulate an informed response to those works that demonstrates an awareness and appreciation of their content, scope, and variety 3. To describe the role of those works as expressions of individual or shared human values within a historical and social context. 4.

Students will acquire the capacity for critical, informed, and creative theological inquiry as a means of deepening their understanding of theological concepts and the human condition. 5. Their study of theology will lead them to examine their own religious experience and to apply theological thought to their personal and professional lives in the service of humanity. 2. World History In an increasingly interconnected society, it is important for students to understand the range of human history in all areas of the world.

Courses in this category focus on the consideration of past events and ideas relative to the States, with the option of including History for a portion of this component area. Courses involve the interaction among 66 individuals, communities, states, and nation, and the world, considering how these interactions have contributed to the development of the United States and its global role

The History component of the Core provides students with an introduction to the political, religious, cultural, economic, and social forces that have shaped the modern world from the origins of humanity to the present. These classes help students develop an understanding of historical causation and expose them to the accomplishments of both Western and non- Western civilizations. By encouraging better appreciation of the factors that created our present society, the History component of the Core enables students to be more effective world citizens.

Courses included in the history category focus on the consideration of past events and ideas relative to the country's, with the option of including history for a portion of this component area. These courses involve the study of the interaction among individuals, communities, states, the nation, and the world, considering how these interactions have contributed to the development of the country and its global role. Courses listed in this area of the core must be designed to help students develop the Student Competencies listed below. Student Competencies 1. To evaluate sources, methodologies, and interpretive strategies historians use to investigate and narrate the past. 2. To articulate and analyse how institutions, cultures, concepts, or relationships change over time. 3. To interpret events, texts, and arguments within their political, economic, cultural, and/or social historical context and as expressions of individual beliefs, values, and decisions. 4.

Students will develop an understanding of the historical factors that created and continue to shape the modern world. 5. They will also come to appreciate the world's many diverse cultures and important contributions they have made. Students should be able to understand how seemingly discrete events are linked over time, and they should learn to read carefully and analyse critically. 3.

Literature The study of literature is a key element in understanding the imagination and the different ways reality can be perceived. The literature component of the Core promotes an 67 appreciation of the text as a creative act and an expression of the human search for meaning. Students are introduced to various methods of interpreting texts that can also enhance inquiry in other fields. Student Competencies 1. Students will attain an understanding of the power of language to shape ideas, values, and the ways men and women are defined. 2. Using critical methods and theories of interpretation, students will be able to analyse and evaluate different cultural, ethical, and aesthetic dimensions of writing and literature. 6. Fine Arts The arts reflect and engage the world around us. They feed the imagination and provide a unique opportunity to study humanity, aesthetics, and cultural values. Courses in

this category focus on the appreciation and analysis of creative artifacts and works of the human imagination. Courses involve the synthesis and interpretation of artistic expression and enable critical, creative, and innovative communication about works of art.

Through courses in art history, studio art, music, or theater, students learn to observe critically, to think creatively, and to appreciate different modes of self-expression and cultural expression.

Courses included in the visual & performing arts component of the core curriculum are designed to help students develop engagement with and aesthetic appreciation of the visual and performing arts; understand works of visual and performing art in their historical, cultural, and social contexts; and/or apply themselves to

creative process or interpretive performance and experience the physical and intellectual demands required of the visual or performing artist.

All courses in the visual and performing arts area of the core curriculum must be designed to help students develop all of the following Student Competencies. Only courses of three hours or more may be included. Student Competencies 1. To demonstrate awareness of the range of works in some area of the visual or performing arts, as well as articulate an aesthetic appreciation of and informed critical response to such works through inquiry, and analysis, evaluation and synthesis of information. 2. To convey interpretative and/or creative responses to artworks by means of effective development, interpretation and expression of ideas through written, oral and visual communication.

68 3.

To evaluate different points of view and to work effectively with others to support a shared interpretative or creative purpose or goal. 4. To analyse how the works being studied and/or created are expressions of individual or broader human values within a historical, cultural or social context, as well as the importance of visual or performing arts in defining or exploring a culture or community. 5.

Students will be able to identify creative expression and to recognize how art reflects and challenges cultural values. 6.

They will demonstrate the ability to evaluate artistic accomplishments. 5. Mathematics

Courses in this category focus on quantitative literacy in logic, patterns, and relationships. Courses involve the understanding of key mathematical concepts and the application of appropriate quantitative tools to everyday experience.

The mathematics Core component promotes proficiency in methods of thought that are inherent to mathematics. These methods include pattern recognition, symbolic abstraction and manipulation, logical and critical analysis, and synthesis.

This component helps students develop an appreciation for mathematical modes of thought, a notion of what mathematical skills entail, the development of some of these skills, and a sense of how mathematical methods can be brought to bear in other fields of study.

Courses included in the mathematics component of the core curriculum are designed to enable the student to competently use mathematical strategies to understand and solve problems. Courses listed in this area of the core must be designed to help students develop the Student Competencies listed below. Student Competencies 1. To accurately manipulate and analyse numerical data using mathematical strategies. 2. To apply appropriate mathematical strategies to solve a given problem and assess the reasonableness of the results. 3. To effectively express and communicate the results of problem-solving using appropriate mathematical language and symbolism. 4.

Students will begin to achieve an understanding of mathematics not simply as a collection of memorized formulas and techniques, but also as a logically developed structure whose abstract methods of problem solving have real-life applications.

69 5. Students will be able to solve mathematical problems and comprehend the logic underlying the solutions 8.

Physical/ natural and Life/ social Sciences - Courses in this category focus on describing, explaining, and predicting natural phenomena using the scientific method. Courses involve the understanding of interactions among natural phenomena and the implications of scientific principles on the physical world and on human experiences. 6. 1

Natural Sciences Scientific inquiry provides a unique way of exploring, knowing, and creating. Courses in science encourage students to think critically about how they can better understand the world around them. These courses help students attain conceptual tools and methodologies to gather, analyse, interpret, understand, and present an array of data. Through the science component of the Core, students develop an understanding of how science benefits and impacts society, empowering them to become active participants in an increasingly complex world.

The Natural Science & Technology component of the core curriculum serves to give students an appreciation of the current state of knowledge in two or more areas of natural science and technology. Courses included in this component of the core curriculum are designed to help students understand the methods, approaches and theories that scientists use to answer questions about the natural world. A total of nine hours is required to complete the core Natural Science & Technology component, including a depth requirement and a breadth requirement. The depth requirement, consisting of six hours of coursework in a single field of study, is intended to introduce students to the most fundamental and important concepts in the natural sciences. The breadth requirement consists of three additional hours of coursework in a second field of study. To satisfy the depth requirement, students must select from the recommended sets of courses listed in the catalogue in the Natural Science & Technology Part I core list. The course selected to satisfy the breadth requirement may come from either the Natural Science & Technology Part I list or the Part II list. Courses listed in this area of the core must be designed to help students develop all Student Competencies listed below. Student Competencies 1. To effectively communicate what scientific theories and methods tell us. 2. To work effectively with others when approaching a scientific problem.

70 3. To identify, analyse, and synthesize the information needed to solve a scientific problem. 4. To accurately apply quantitative methods when solving scientific problems. 5.

Students will be able to understand and engage in the process of scientific inquiry. 6. They will become familiar with methodological approaches that enable natural scientists to evaluate and solve problems effectively. 7. Students will also appreciate how the scientific process combines technical and creative aspects and depends on the cooperation and interaction of scientists with each other. 6.2 Social Sciences

Courses in this category focus on the application of empirical and scientific methods that contribute to the understanding of what makes us human. Courses involve the exploration of behaviour and interactions among individuals, groups, institutions, and events, examining their impact on the individual, society, and culture. Courses included in the social or behavioural sciences component area of the core curriculum are designed to help students understand the methods, approaches, and theories that social scientists have developed to understand societies and the relationship of individuals to societies. :

As future leaders in a complex and inter-related society, students need to understand the human and social world around them. Social science courses promote this understanding by providing knowledge and methodologies that help students examine the foundations of human behaviour and the origins and consequences of social institutions. Tools of systematic social inquiry introduced in these classes enable students to construct and critically assess claims about social life and to become more effective and ethical problem solvers. Social science courses help students appreciate how their personal and professional actions can accommodate the world's diversity and promote a more peaceful and just society at all levels of citizenship.

All courses in this area of the core curriculum must be designed to help students meet the following Student Competencies. Student Competencies 1. To demonstrate an understanding of empirical methods, approaches, technologies that social and behavioural scientists use to investigate the human condition, as well as the resulting data, and to communicate these understandings effectively.

71 2.

To examine social institutions and processes across a range of historical periods, social structures, and cultures. 3. To analyse the effects of historical and social forces on regional, national, and global communities. 4.

Students will acquire conceptual tools and methodologies to analyse and understand their social world. With these tools, they will be able to act in their world more effectively and become forces for positive change. 5. They will gain a better understanding of human diversity. Students will be able to think and write critically about human behaviour and community. 6. They will become aware of the various methodological approaches used by social scientists. 7.

Political Science Courses in this category focus on consideration of the Constitution of the States and the constitutions of the states, with special emphasis on that which want to teach. Courses involve the analysis of governmental institutions, political behaviour, civic engagement, and their political and philosophical foundations. Courses included in the core component area must focus on consideration of the Constitution of the States and the constitutions of the states. These courses involve the analysis of governmental institutions, political behaviour, civic engagement, and their political and philosophical foundations. A total of six hours is required to complete this component area and must include at least one course with special emphasis on the constitution. Courses listed in this area of the core must be designed to help students develop Student Competencies one through four. Courses listed in this area of the core, which include a special emphasis on five competency of the students . Student Competencies 1. To demonstrate a broad understanding of political behaviour and institutions in the States, including detailed knowledge of the Constitution of the States and its origins. 2. To apply basic social science concepts and theories to develop and evaluate social science data. 3. To organize and express ideas in a clear and logical fashion through written, oral, or visual communicative messages.

72 4. To analyse the role of civic duties, personal and social responsibility, and ethical decision-making as they relate to political behaviour. 5. To demonstrate a broad understanding of political behaviour and institutions, including detailed knowledge of the constitution and its origins. Expanded Core

Curriculum The term

expanded core curriculum (ECC) is used to define concepts and skills that often require specialized instruction with students who are blind or visually impaired in order to compensate for decreased opportunities to instruction with students who are blind or visually impaired in order to compensate for decreased opportunities to learn incidentally by observing others.

In addition to the general education core curriculum that all students are taught, students with visual impairments, starting at birth, also need instruction in the ECC. The ECC areas include (A)

needs

that result from the visual impairment that enable the student "to be involved in and make progress in the general education curriculum?"

and (

B)

other educational needs that result from the child's disability"

as required by IDEA

require the flexibility of

school districts to make

73 arrangements for services to occur "beyond regular school hours to ensure the student learns the skills and receives the instruction" in the ECC.

The

Expanded Core Curriculum

compensatory or functional academic skills, including communication modes

orientation and mobility social interaction skills independent living skills recreation and leisure skills career education

use of assistive technology

sensory efficiency skills

Self-determination The Expanded Core Curriculum

Nine Unique Educational Needs for

Students with Visual Impairments

The Expanded Core Curriculum (ECC) is the body of knowledge and skills that are needed by students with visual impairments due to their unique disability specific needs.

Students

with visual impairments need the expanded core curriculum in addition to the core academic curriculum of general education.

The ECC should be used as a framework for assessing students, planning individual goals and providing instruction. The expanded core curriculum is a set of skill areas developed to augment the traditional core curriculum. The expanded core curriculum includes areas of instruction specific to students with visual impairments. Intervention from a teacher for students with specific to students with visual impairments. Intervention from a teacher for students with visual impairments is necessary to provide direct instruction in the expanded core. What does IDEA say about the expanded core curriculum (ECC)? •••• Each disability requires that a broad set of disability-specific skills and abilities be addressed. For students with visual impairments, the disability-specific skills are within nine domains and collectively known as the "expanded core curriculum" (ECC). When the domains in the ECC are systematically and intentionally addressed by all members of the instructional team, the student's independence and readiness for the post-school environment are dramatically improved. A visual impairment can affect all areas of functioning, well beyond the classroom. The ECC extends beyond reading, writing, and calculation. It includes those skills necessary to benefit from instruction in the core curriculum and to achieve functional independence. ••••

The

ECC stems from the following IDEA requirements for evaluations: For children who are blind or visually impaired, evaluations to document the present level of academic and functional performance for the development of the individualized education program (IEP) are required by the federal Individuals with Disabilities Education Act 74 ••••

And specially designed instruction:

Specially designed instruction means adapting, as appropriate to the needs of an eligible child under this part, the content, methodology, or delivery of instruction to address the unique needs of the child that result from the child's disability. •••• Assumptions: While the concepts and skills affiliated with the expanded core curriculum (ECC) have been described for many years as those needed for students with visual impairments, the term "expanded core curriculum" (or "ECC") may be new to administrators, and possibly to VI professionals. Assessment and instruction for students with visual impairments in the ECC domains may be completed by the VI professional, or other members of the educational team, including family members. Districts

that

have not been active in ensuring that each student has been assessed in all of the ECC'

The two things I use every day of my life are social skills and orientation and mobility skills. . . . Those were the lowest priorities for my teachers when I was in school.' (K. Carley, an adult with a visual impairment in a speech to the International Council for Education of People with Visual Impairments.)

Every parent wants their child to have meaningful social relationships. For parents, this is not an "optional" activity. It is critical to a satisfying life and success in a job. The ECC Districts

who have not been active in ensuring that each student has been assessed in all of the ECC domains, may develop a plan to identify priority domains and timelines for completion of the assessments. While all students should be periodically assessed in all of the ECC domains, not all students will require instruction in every domain every year. Due to the non-traditional, but required nature of the ECC domains and the requirement in IDEA that instruction takes place in the home, school, and community, districts may need.

As per IDEA: Specially designed instruction means adapting, as appropriate to the needs of an eligible child under this part, the content, methodology, or delivery of instruction to address the unique needs of the child that result from the child's disability.

From

IDEA regarding evaluations: For children who are blind or visually impaired, evaluations to document the present level of academic and functional performance for the development of the individualized education program (IEP) are required by the federal Individuals with Disabilities Education Act. From IDEA regarding specially designed instruction:

Specially

designed instruction means adapting, as appropriate to the needs of an eligible child under this part, the content, methodology, or delivery of instruction

75 to address the unique needs of the child that result from the child's disability. "Specially designed instruction" for students with visual impairments, and based on assessment, specially designed instruction

is the expanded core curriculum (ECC). The "expanded core curriculum" refers to the knowledge, concepts, and skills typically learned incidentally by sighted students that must be sequentially presented to the student who is blind or has low vision. The expanded core curriculum

areas include: 1.

Needs

that result from the visual impairment to enable the student "to be involved in and make progress in the general education curriculum?"

And 2. Other educational needs that result from the child's disability"

as required by IDEA.

The presence of a visual impairment requires that these skills be thoroughly evaluated and systematically taught to these students by teachers with specialized expertise. Without specialized instruction, children with vision loss may not be aware of the activities of their peers or acquire other critical information about their surroundings. 1.7.5

Need of Expanded Core Curriculum: Every student is expected to leave high school with a strong grasp of "core" subjects like math, language arts, science, and history.

But in order to master these subjects, and to eventually live and work independently, students who are blind or visually impaired must learn an additional set of skills known as the "expanded core curriculum."

Essential life skills including social interaction, independent living, career education, and communication modes such as braille, must be taught alongside basic academics.

For a student who is blind, learning about world geography from books is not enough. That student must also learn orientation and mobility skills and practice using a white cane for safe, independent travel.

The expanded core curriculum empowers students with disabilities to access their education and make their own choices throughout life.

Whether they are socializing and learning to handle money in the student store, finding their own way to classrooms across campus, or playing adapted sports in gym class, students are building a foundation for success in life at Perkins and beyond. "If students do not have these skills in place, they cannot become productive, independent adults," Teaching students with visual impairments in public schools while sighted children use visual experiences throughout their lives to learn concepts casually or incidentally, students who are visually impaired with or without additional disabilities cannot rely on sensory observations.

The foundational skills they need for daily life in school, at home, and in the community, must be strategically taught and integrated into all aspects of their

76 education.

The

ECC areas include: compensatory skills, including communication modes (adaptations needed for students to access core subjects such as braille, sign language, or tactile symbols);

orientation and mobility; social interaction skills; independent living skills; recreation and leisure skills; career education; assistive technology;

sensory efficiency skills;

and self-determination.

To prepare lunch, students must plan the meal, shop for ingredients, and help out in the kitchen with everything from chopping carrots to cleaning dishes. The assignment requires students to practice orientation and mobility, independent living skills including handling money and cooking, reading recipes in braille, social interaction, and self-determination. "It takes a lot of practice for students to integrate these skills into their bodies and minds," parents to work closely with teachers of the visually impaired to ensure ECC skills such as the use of assistive technology, career education, and independent living, are well incorporated into their child's individual education plan (IEP).

In short, systematically addressing the expanded core curriculum (ECC) makes a dramatic difference on how prepared students are for their next environment.

Consider: Students with visual impairments attend postsecondary institutions at a rate that is comparable to students without disabilities. 29.4% of students with visual impairments are competitively employed versus 69% youths in general. 46.4% of students with visual impairments live independently versus 60% youths in general. "Vocational skills training for youths with visual impairments needs to incorporate the use of compensatory skills." Having ECC skills makes "the difference between life and a successful life." "Students who receive high-quality instruction in the ECC have a 'richer quality of life' than do those who do not".

Education director about changing to an ECC-based program. What is the role as an administrator? As an administrator, have the unique role of ensuring that the ECC will be implemented in own district. Implementation will include issues related to staffing, service provision, and professional development.

Let's get started! Role of VI professionals in the ECC and staffing issues

Teachers certified in visual impairments (TVIs) and orientation and mobility specialists (COMS/O&Ms) certainly play a large role in providing assessment and instruction in the ECC. VI professionals are not the only key players. They provide: assessment and evaluation, direct instruction, consultation, collaboration, and facilitation with community and state wide resources. However, the scope of the competencies in the ECC and the need for instruction in the home, school, and community will require increased participation and creativity. VI professionals and others may require periodic changes in work shifts, collaboration with non-traditional partners, and various types of transportation support. Solid 77 supervisory/administrative support also includes ensuring that there is: evidence of ECC assessments in evaluation reports, evidence of IEP goals based on ECC evaluations, and evidence of ECC instruction during staff observations, including the performance evaluation.

There are innumerable ways to support this change to an ECC-based VI program. Here are just a few examples: Support training for VI/O&M staff on addressing ECC needs through conferences, regional service centres, and other professional development activities. Provide resources for on-going

data collection to VI/O&M staff to complete ECC checklists/evaluations as part of FVE/LMA and O&M evaluations.

Provide strong support and time for collaborative team discussions on multidisciplinary approaches to addressing student ECC needs. Collaboration requires time? Without it, meetings collapse or become non-productive. Encourage creativity to meet the ECC instructional options. Consider time outside of the regular school day to accomplish ECC instruction Flexible schedules before and after school. Summer instruction Facilitate transportation Facilitate community exploration and experiences

Student information needed to support either a caseload analysis or the ECC is very similar. Each will support the other. Starting with assessment as in other programmatic areas, a VI program based on the ECC requires plans for assessment and instruction. Many districts find that they have not completed assessments in all areas of the ECC. The VI professional or other team member may say "She/He can do that," but not have data to show whether target behaviour is age appropriate or generalizes to other settings or environments. For example, the classroom social skills may not be the skills most desired on the playground, at church, or in a social gathering.

The hardest part is just getting started. However, armed with a plan and a timeline, completing assessments in all required areas can be accomplished. ❖❖❖❖❖ Evaluate student needs Review the existing documentation about the students. Look for the following documents: ●●●● Eye examination report ●●●● Referral and parental permission ●●●● Functional vision evaluation and learning media assessment ●●●● Additional evaluations, such as an O&M evaluation, assistive technology, adapted P.E. evaluation, clinical low-vision evaluation, and others, depending on individual students. ●●●● Data-driven evaluations in all areas of the ECC. Multiple formal and informal evaluations and checklists exist. Two excellent resources are Evals: Evaluating

78 Visually Impaired Students from TSBVI and ECC checklists, including those developed by Education Service Centre. ❖❖❖❖❖ Prioritize domains for additional assessment. It isn't always possible to address all areas that may arise from your review at once. Gather feedback from students, parents, general and special educators, and support staff. Then determine a plan to address areas of concern as you build capacity ensuring that in the future all students are fully assessed. For example, set goals for the next round of assessments, including: Domains that are especially sparse will be an early focus. ❖❖❖❖❖ Develop an assessment plan Gather your resources It all starts with a plan. It doesn't have to happen all at once.

Access to the ECC has provided the vehicle for transforming students with visual impairments' independence and opportunity for enhanced postsecondary outcomes. Special Education director about changing to an ECC-based program.

Once your priorities are set, determine how you will address the additional evaluations needed.

Resources like Evals: Evaluating Visually Impaired Students (TSBVI) can be invaluable. Evals provides a detailed listing of specific areas addressed in school curricula.

While the names and

organizations will differ from state to state, the knowledge and skills will be equivalent. Evals has thousands of specific skills that can use to form checklists to meet your specific needs. The ECC Checklists from the Region 10 Education Service Centre bring all of the Evals data into a single document. The checklists can also be used to track progress over a period of years.

An

important consideration when using multiple assessment partners, especially when using checklists, is having a common understanding of the criteria for completion. This can be a common problem when one person thinks a student's skill is "good enough" and another thinks it is still "emerging." This can be due to expectations or issues in generalizations across environments. Regardless, consistency in scoring is a key factor to viable assessments. One way to ensure consistency in scoring criteria is to have a common scoring tool used across as many assessments as is reasonable. One tool could be the scoring criteria developed by Functional Resources, Inc. for the Functional Skills Screening Inventory. There is a basic one and variations for different environment and employment situations. Determine who will complete which necessary assessments. Some skills can be assessed in special education classes, including early childhood and life-skills type classes. General educators, including vocational and physical education specialists, are valuable assessment partners. Parents can assist with assessments in the home and community. Students may attend special events, such as workshops or camps, where the assessments take place. The assessment

79 partners may need training on how to use specific assessment instruments. It may be as little as helping them understand the criteria for "independent" on a checklist, or it may be more extensive. If more extensive help is needed, professional development should be part of the implementation plan and the schedule should be adjusted as appropriate.

Depending on plan to develop comprehensive evaluations for the ECC, schedule for assessments may be part of the re-evaluation process. Or the assessments may be scheduled to happen during the year in accordance with other academic and non-academic events. It could also take place during the summer, or while on field trips. The important thing is to have a schedule, one that is well known and viable for all team members. Embarking on a direct and high-quality program to support instruction in the expanded core curriculum (ECC) requires commitment and knowledge.

The ECC has also made it easier for collaboration and co-treat models in for O&M, as well as speech, OT and AT. Special Education director about changing to an ECC-based program.

Ø Commit to the change.

With a clear understanding of the expanded core curriculum, you are ready to guide your program to the next step in excellence. As a team, you and the VI professionals in your district will develop the resources and skills to implement this proactive change. The commitment to move to ECC-based programming may be a significant change and may affect many areas of the program, ranging from how educators and support staff spend their time, how professionals develop plans and approaches, to how educational teams interact. However, the result will be students who are better able to (a) benefit from the core curriculum, (b) transition to and function in their next environment, and (c) engage in a variety of social and career options with safety and confidence.

Ø

Once the information is gathered from checklists, screenings, or other evaluations, the next step is to determine priorities, both for individual students and the program as a whole. It is possible that a review of all (or a sample of) the summary checklists indicates that many of your students have limited understanding in one or more areas. If so, then a plan to address the professional development and the acquisition of necessary resources will be needed.

Ø The challenge is to think outside of the box and find more focused means of meeting the ECC program goals? to develop and use new collaborative relationships and use available time in more varied ways. Ø Ensure that VI professionals focus and teach only in expanded core domains. Other educators have the expertise and are available to teach core topics.

Eliminate

80 tutoring from the VI professional's day. If a student is having trouble in a core area, is it because she or he doesn't know how to use the tools needed to access the information? Or is the reason more content-driven? For example, if a student is having trouble with spelling, the TVI will help if she can't use her magnifier to read the spelling words, but if she is having trouble remembering how to spell, someone else is better suited. Ø Examine strengths and weakness in VI professionals. When a TVI or O&M specialist is unsure or unskilled and is responsible to working in a domain, the instruction will be less efficient, less effective, and will require more time. Help VI professionals in your district access the needed professional development and ensure that the new skills get implemented into daily routines. Develop appropriate and shared responsibilities of all team members. This may require new relationships, or changes in existing partnerships. Ø Given the scope of the ECC and the range of caseloads, it is expected that some level of professional development will be needed. In addition to what neighbouring, regional, and state educational organizations and agencies provide, an increasing

Social skills and assistive technology are particular areas I note intense student growth. Special Education director about changing to an ECC based program.

Amount of targeted professional development options are available. More and more organizations are offering training via distance learning options, either through webinars, compressed video networks (interactive television systems), or any combination of like approaches. Also, since many distance learning training options are either free or have a single cost attached, more members of the student's educational team may attend, thereby incorporating the new information into a variety of learning environments.

Ø

For some districts, incorporating the ECC will be a big change. It may be part of a 2-3-year plan to move toward excellence. Also, given the scope of the expanded core curriculum, it may require considerations in instructional and staffing arrangements. Below is brief listing of various options for your consideration as you and your VI professionals map out this new programmatic approach to visual impairments.

Direct instruction with the VI professional(s) This may or may not be different from how instruction is currently delivered. The focus of the instruction may shift. Rather than providing tutoring services, the VI professional may instead increase instruction in how to access the general curriculum using, for example,

81 low-vision devices. Or instruction may occur more often out of the classroom, off the campus and into the community for vocational programming. Ø Collaboration with other team members, including parents and community organizations

Collaboration, or collaborative consultation, is an active process that takes place in the student's learning environment -whether home, school, or community. The VI professional may be present in classrooms and learning environments not visited previously, such as the home economics class, work programs, or home. Collaboration may also happen with community programs, such as Girl Scouts or various hobby-related groups, such as horseback riding or sports programs. Regional and state wide events can also provide experience and instruction in the expanded core curriculum domains.

Ø Many states have access to summer and holiday programs through a variety of sources. These may include camps, such as those sponsored by: Lion's Clubs, short-term programs at residential schools rehabilitation organizations Lighthouse for the Blind independent living centre's regional education service centre's adult mentoring can also be a very powerful tool. When students are connected with an adult with a visual impairment, they (and their parents) can get a better understanding of what will be expected of them once they leave the school system. Ø For many districts, moving to an ECC-based program may be a big change and may require more than 1 year to complete. Here are a few tips for supporting this change: Remember options for addressing the ECC. Provide strong support and ample time for collaborative team discussions on multidisciplinary approaches to addressing students' ECC needs.

Provide resources for on-going data collection to VI/O&M staff to complete ECC checklists/evaluations as part of functional vision evaluations/learning media assessments and O&M evaluations. Expect data collection and assessments to be part of standard instructional practices. Support training for VI-related team members on addressing ECC needs through conferences, regional service centres, TSBVI Outreach, and the like. Ø When using multiple people to assess students and collect data, ensure that there is a common understanding of criteria and ratings. Work with VI professionals to find solutions for addressing ECC goals. Consider using time outside of the regular school day, including the use of exchange and/or comp time, instruction before and/or after the school day, and summer instruction. Provide support for transportation and community exploration and experiences.

82 1.7.6 Components of Expanded Core Curriculum: The Nine Components or domains of the Expanded Core Curriculum are as follows: ●●●● Compensatory or functional skills:

Compensatory or functional skills needed to access the general curriculum. Literacy- related areas, such as braille, handwriting skills, low-vision devices and tactual or object symbols.

Compensatory and functional academic skills, including communication modes.

Communication, including alternative communication systems, such as tactile or object- oriented systems.

Compensatory skills involve the adaptations necessary for accessing the core curriculum, which can include: braille, tactile symbols, sign language, and recorded materials. On the other hand it may be say that Compensatory or Functional Academic Skills, Including Communication Modes (Note: for this area of

the expanded core curriculum for blind and visually impaired students, a distinction must be made between compensatory skills and functional skills.

Compensatory skills are those needed by blind and visually impaired students in order to access all areas of core curriculum.

Mastery of compensatory skills will usually mean that the visually impaired student has access to learning in a manner equal to that of sighted peers. Functional skills refer to the skills that students with multiple disabilities learn that provide them with the opportunity to work, play, socialize, and take care of personal needs to the highest level possible.).

in many cases it find that

Compensatory and functional skills include such learning experiences as concept development, spatial understanding, study and organizational skills, speaking and listening skills, and adaptations necessary for accessing all areas of the existing core curriculum. Communication needs

will vary, depending on degree of functional vision, effects of additional disabilities, and the task to be done. Children may use braille, large print, print with

the use of optical devices, regular print, tactile symbols, a calendar system, sign language, and/or recorded materials to communicate.

Regardless, each student will need instruction from a teacher with professional preparation to instruct students with visual impairments in each of the compensatory and functional skills they need to master. These compensatory and functional needs of the visually impaired child are significant, and are not addressed with sufficient specificity in the existing core curriculum.

So it will find

Compensatory skills include skills necessary for accessing the core curriculum including concept development?

Communication modes? Organization and study skills? Access to print materials?

and the use of braille/

Nemeth,

tactile graphics, object and/or tactile symbols, sign language, and audio materials.

Or Compensatory or functional academic skills, including communication modes-skills that a student with a visual impairment must

83 acquire to access the regular curriculum. These skills include learning braille, study and organizational skills, spatial understanding, and any adaptation of the existing curriculum. ●●●●

Orientation and Mobility:

Orientation and mobility instruction enables students of all ages and motor abilities to be oriented to their surroundings and to move as independently and safely as possible.

Travel skills start in infancy and are not restricted to only those who are mobile, blind, or are without additional disabilities.

Students learn about themselves and their environments, including home, school, and community. O&M lessons incorporate skills ranging from basic body image, spatial relationships, and purposeful movement to cane usage, travel in the community, and use of public transportation. Having O&M skills enables students to acquire independence to the greatest extent possible, based on their individual needs and abilities.

As a part of the expanded core curriculum, orientation and mobility is a vital area of learning.

Skills

to orient children who are

visually impaired to their surroundings and travel skills

to enable them to move independently and safely in the environment.

Teachers who have been specifically prepared to teach orientation and mobility to blind and visually impaired learners are necessary in the delivery of this curriculum.

Students will need to learn about themselves and the environment in which they move from basic body image to independent travel in rural areas and busy cities.

The existing core curriculum does not include provision for this instruction. It has been said that the two primary effects of blindness on the individual are communication and locomotion. The expanded core curriculum must include emphasis on the fundamental need and basic right of visually impaired persons to travel as independently as possible, enjoying and learning from the environment through which they are passing to the greatest extent possible.

In these skills involved in independent travel and the concepts that underlie spatial reasoning and navigation. Safe and efficient travel throughout the environment. This procedure fully possible by the help of a specialized instruction, such as numerous methods to represent spatial, environmental, and temporal and/or body concepts, including those too small, large, or dangerous to be experienced directly. ●●●●

Social Interaction Skills: Social interaction skills include awareness of body language, gestures, facial expressions, and personal space. Instruction also includes learning about interpersonal relationships, self-control, and human sexuality.

Almost all social skills are learned by visually observing other people. Instruction in social interaction skills in school, work, and recreational settings is crucial.

Almost all
social skills

used by sighted children and adults have been learned by visually observing the environment and other persons, and 84 behaving in socially appropriate ways based on that information. Social interaction skills are not learned casually and incidentally by blind and visually impaired individuals as they are by sighted persons. Social skills must be carefully, consciously, and sequentially taught to blind and visually impaired students.

Nothing in the existing core curriculum addresses this critical need in a satisfactory manner. Thus, instruction in social interaction skills becomes a part of the expanded core curriculum as a need so fundamental that it can often mean the difference between social isolation and a satisfying and fulfilling life as an adult.

Or it may be say that

having appropriate social skills

can often mean the difference between social isolation and a fulfilling life as an adult.

Since nearly all social skills are learned by observation of the

environment and people, this is an area where students with vision loss need careful, conscious and explicit instruction.

Because acquisition of the subtle modes of interaction that people develop by watching, imitating, and reacting to each other. Where

visual impairments can socially isolate a student and affect his or her ability to benefit from innumerable non-verbal social cues. This can have an effect on the student's personal life and future employment. •••••

Independent Living Skills: Independent living skills include the tasks and functions people perform in daily life to increase their independence and contribute to the family structure. These skills include personal hygiene, eating skills, food preparation, time and money management, clothing care, and household tasks.

This area includes

the tasks and functions people perform in daily life to optimize their independence - skills such as personal hygiene, food preparation, money management, and household chores.

This area of the expanded core curriculum is often referred to as "daily living skills."

It consists of all the tasks and functions persons perform, in accordance with their abilities, in order to lead lives as independently as possible. These curricular needs are varied, as they include skills in personal hygiene, food preparation, money management, time monitoring, organization, etc.

Some independent living skills are addressed in the existing core curriculum, but they often are introduced as splinter skills, appearing in learning material, disappearing, and then reappearing. This approach will not adequately prepare blind and visually impaired students for adult life. Traditional classes in home economics and family life are not enough to meet the learning needs of most visually impaired students, since they assume a basic level of knowledge, acquired incidentally through vision.

The skills and knowledge that

sighted students acquire by casually and incidentally observing and interacting with their environment are often difficult, if not impossible, for blind and visually impaired students to learn without direct, sequential instruction by 85 knowledgeable persons.

The myriad of skills that assists with living is primarily learned visually. Students with visual impairments are likely to need structured instruction in personal, financial, and/or home management skills. Family members may help facilitate learning these skills.

People with vision typically learn such daily routines through observation, whereas individuals with visual impairments often need systematic instruction and frequent practice in these daily tasks.

It can include cooking, personal hygiene, money management, time monitoring, and organization. These are often skill areas that children with visual impairments do not develop because they do not observe them in others and they are often not explicitly taught. •••••

Recreation & Leisure Skills:

Skills to ensure students' enjoyment of physical and leisure-time activities, including making choices about how to spend leisure time.

Skills in recreation and leisure are seldom offered as a part of the existing core curriculum. Rather, physical education in the form of team games and athletics are the usual way in which physical fitness needs are met for sighted students.

Many of the activities in physical education

are excellent and appropriate for visually impaired students. In addition, however, these students need to develop activities in recreation

and leisure

that they can enjoy throughout their adult lives. Most often sighted persons select their recreation and leisure activity repertoire by visually observing activities and choosing those in which they wish to participate.

The teaching of recreation and leisure skills to blind and

visually impaired students must be planned and deliberately taught, and should focus on the development of lifelong skills. That while physical fitness is generally addressed in the regular curriculum, activities that can be used to actively fill leisure time are often not addressed. Without direction instruction, it is not likely that a child will be exposed to the range of activities possible.

Students need to be exposed to recreation and leisure activities, as exposure may not happen incidentally. Students should be made aware of modifications needed to make an activity accessible.

Being unable to observe others reduces awareness of recreation and leisure options. Instruction in recreation and leisure skills will ensure that students with visual impairments will have opportunities to explore, experience, and choose physical and leisure-time activities, both organized and individual, that they enjoy. This instruction should

focus on the development of life-long skills. •••••

Career Education:

Career education-

as in many of the other areas listed, children with visual impairments are often not exposed to a large variety of career options. This is both because of a lack

86 of prior visual experiences and because of a perception that the range of options is severely limited for children with visual impairments. Unemployment and underemployment is one of the biggest problems facing adults with visual impairments in today's society.

Students with vision loss benefit most from an experiential learning approach. Structured visits to community sites and discussions with people who perform various jobs, enable them to understand concepts and specific skills that are needed to be successful in those jobs.

Considering the national rate of unemployment or underemployment of working-age adults who are blind is 70% -75%, this area needs attention throughout the school years to help students with vision loss develop marketable job skills.

With limited ability to learn about employment options via observation, students need to be taught about the various types of career options and the skills necessary to achieve personal goals.

Career education will provide students with visual impairments of all ages the opportunity to learn through hands on experiences about jobs that they may not otherwise be aware of without the ability to observe people working. They also learn work-related skills such as assuming responsibility, punctuality, and staying on task. Career education provides opportunities for students to explore and discover strengths and interests and plan for transition to adult life.

There is a need for general vocational education, as offered in the traditional core curriculum, as well as the need for career education offered specifically for blind and visually impaired students. Many of the skills and knowledge offered to all students through vocational education can be of value to blind and visually impaired students.

They will not be sufficient, however, to prepare students for adult life, since such instruction assumes a basic knowledge of the world of work based on prior visual experiences. Career education in an expanded core curriculum will provide the visually impaired learner of all ages with the opportunity to learn first-hand the work done by the

bank teller, the gardener, the social worker, the artist, etc. It will provide the student opportunities to explore strengths and interests in a systematic, well-planned manner. Once more, the disadvantage facing the visually impaired learner is the lack of information about work and jobs that the sighted student acquires by observation. Because unemployment and underemployment have been the leading problem facing adult visually impaired persons in the United States,

this portion of the expanded core curriculum is vital to students, and should be part of the expanded curriculum for even the youngest of these individuals. •••••

Assistive Technology: Assistive technology is a powerful tool that can enable students with vision loss to

87 overcome some traditional barriers to independence and employment.

Assistive technology is an umbrella term that includes assistive and adaptive tools as well as instructional services that can enhance communication, access, and learning.

Access to information in "real time" is a key issue for students with visual impairments. High- and low-tech strategies may be critical for students to access the general curriculum and enhance communications.

Use of assistive technology can be a great tool for providing access to information for people with visual impairments.

Whether it is through speech, braille, or large print output, the use of technology gives a person with a visual impairment access to information at approximately the same time as a person who is sighted. It

can include electronic equipment such as switches, mobile devices, and portable notetakers? computer access such as magnification software, screen readers, and keyboarding? and low-tech devices such as an abacus, a braille, Active Learning materials (e.g., Little Room®), and optical devices.

Technology is a tool to unlock learning and expand the horizons of students.

It is not, in reality, a curriculum area. However, it is added to the expanded core curriculum because technology occupies a special place in the education of blind and visually impaired students. Technology

can be a great equalizer. For the braille user, it allows the student to provide feedback to teachers by first producing material in braille for personal use, and then in print for the teacher, classmates, and parents. It gives blind persons the capability of storing and retrieving information. It brings the gift of a library under

the fingertips of the

visually impaired person. Technology enhances communication and learning, as well as

expands the world of blind and visually impaired persons in many significant ways.

Thus, technology is a tool to master, and is essential as a part of the expanded core curriculum. ●●●●

Sensory Efficiency Skills:

Sensory efficiency includes instruction in the use of vision, hearing, touch, smell, and taste.

It also addresses the development of the proprioceptive, kinaesthetic, and vestibular systems.

Learning to use their senses efficiently, including the use of optical devices, will enable students with visual impairments to access and participate in activities in school, home, and community environments.

Students are likely to need structured and systematic instruction in visual, tactual, and auditory skills in order to benefit from other areas of the general curriculum and the expanded core curriculum.

Or these skills are

help students use the senses - including any functional vision, hearing, touch, smell, and taste - to access skills related to literacy and concept development.

But now a day sensory efficiency includes instruction in

the use of residual vision, hearing, and the

other senses? for example, learning how to use optical devices, hearing aids, augmentative communication devices, and the like. In addition, learning how to integrate

all remaining senses to counter the impact of any missing or impaired sense is also integral to this area?

for example, learning how to use tactual, gustatory, and olfactory input rather than visual cues to identify one's personal possessions, or using hearing and the other senses to identify people one knows without visual cues, fits into this area.

Visual efficiency skills that although the amount and type of vision varies greatly among individuals, a common requirement is instruction in using what vision they have efficiently. For a student with a field loss, it might be viewing print eccentrically to maximize clear perception of the print. For another student it might be paying attention to objects in their peripheral field when walking to get as much advance warning of impending obstacles as is possible. Every person's situation will be different: that is why it is important to involve the TVI in the development of the activities designed to answer the needs outlined in the expanded core curriculum. ●●●●

Self-Determination: Self-determination includes decision-making, self-advocacy, and individual responsibility. These skills lead to competence, as opposed to "learned helplessness," and are appropriate for all students, at all ages and abilities.

It also

includes choice-making, logic-making, problem solving, personal advocacy, assertiveness, and goal setting. Students with visual impairments often have fewer opportunities to develop and practice the specific skills that lead to self-determination. Students who know and value who they are and who have self-determination skills become effective advocates for themselves and therefore have more control over their lives.

Skills to enable students to become effective advocates for themselves based on their own needs and goals.

In

this

area of the ECC

highlights the importance of believing in oneself, while understanding one's abilities and limitations.

Students learn from successes and failures how to achieve one's goals in life. Self-determination is the ability for people to control their lives, reach goals they have set and take part fully in the world around them. Bringing together all of these skills learned in the expanded core curriculum produces a concept of the blind or visually impaired person in the community. It is difficult to imagine that a congenitally blind or visually impaired person could be entirely at ease and at home within the social, recreational, and vocational structure of the general community without mastering the elements of the expanded core curriculum. What is known about congenitally blind and visually impaired students is that, unless skills such as orientation and mobility, social interaction, and independent living are learned, 89 these students are at high risk for lonely, isolated, unproductive lives. Accomplishments and joys such as shopping, dining, attending and participating in recreational activities are a right, not a privilege, for blind and visually impaired persons. Responsibilities such as banking, taking care of health needs, and using public and private sectors. 1.8 Let Us Sum Up Curriculum refers

to the total structure of ideas and activities developed by an institution to meet the needs of students and to achieve the desired educational aims.

A well designed and properly implemented curriculum can help aesthetic, emotional, ethical, intellectual, physical, social, spiritual and vocational development of a child.

Curriculum

is needed for national development, developing democratic life, rising standard of living, national integration and international understanding. Curriculum is all short experiences gained by the students in school through various planned activities and informal activities with the support teachers. 1.9 Check Your Progress 1. Describe the significance and need of curriculum. 2. Describe different types of curriculum. Which type of curriculum do you prefer? Discuss briefly. 3. What are the major factors that lead to the efficient implementation of the curriculum? 4. What are the various approaches to curriculum development? Explain one of them. 5. Write the needs of expanded core curriculum in special education. 6. What is core curriculum? Explain the difference between core curriculum and expanded core curriculum. 1.10 References 7. Teaching Functional Academics Skills Structure 2.1 Introduction 2.2 Objectives 2.3

Learning Media Assessment 2.4 Braille Reading Readiness 2.5 Techniques of Teaching Braille 2.6 Techniques of Teaching Print to Children with Low Vision 2.7 Braille Aids and Devices, Optical Devices for Print Reading and Writing 2.8

Let Us Sum Up 2.9 Check Your Progress 2.10 References 2.1 Introduction

Functional academic skills are the important part for a blind person's life like other people. Because of its usefulness it is too much important to know how a visual impaired person develops his ability in learning efficiency. Functional academics means—literacy (reading and writing), basic math, time and money skills, Self-care skills, domestics, recreation, community experiences, Formal employment opportunities which all are beginning in middle school. On the other hand it must be in mind if the procedure of teaching these skills is following absolute correct method then the learning capacity of a child is easier or it must be said that the child can be able to use the skills totally. Learning media assessment, braille reading writing capacity and use print material in developing ability is come under functional academic skills. Or it may be said that these abilities are the major part of the functional academic skills. In this unit discuss about the process for developing functional academic skills. 2.2 Objectives After going through this unit you will able to: 1. Describe various types of aids which are used in braille learning.

93 2. Explain the procedure of pre braille teaching methods. 3. List out the optical devices used in reading and writing. 4. Discuss the necessary for assess of learning media. 5. Follows the teaching techniques of braille. 2.3 Learning and Media Assessment

The

Learning Media Assessment (LMA) offers a framework for selecting appropriate literacy media for a student who is visually impaired. A Functional Vision Assessment (FVA) should be done first, in order to determine what the student is able to see and how he or she is using his or her vision. These two assessments should be used together to help to guide the team decision about the best instructional medium for a given student, such as braille, print, dual media (both print and braille), auditory, tactile or some combination.

Learning Media Assessment is

an assessment for selecting the appropriate literacy media for students with visual impairments. "

Literacy media" refers to the way in which students access the general education curriculum and includes braille, print, auditory strategies, objects, and pictures,

offers teachers and educational teams a framework or decision making process for the selection of literacy media, provides a

decision

and monitoring tool for both conventional and functional literacy for students with visual impairments, Involves a team process and the collation of medical, educational, family and student supplied data to make informed decisions.

The

LMA assesses a student's learning style, or the way in which he or she uses vision, touch, hearing, and other senses, either singularly or in combination, to gain access to information. This is where LMA has often been misunderstood. One of the key things that

are

assessed is the student's learning style, which is particularly useful when working with young children with visual impairments. The LMA scale should begin no later than age 3, when a child begins the transition to preschool. It should be updated annually and/or as visual functioning changes. This scale can be used academically for students who are in the general education curriculum and proceeding along an academic track. However, it should also be used with children with more complex disabilities in looking at functional literacy. LMA takes a broad definition of literacy, which includes reading and writing in some form, such as using drawing or expressive communication. Some Teachers of the Visually Impaired (TVIs) only look at the braille/print decision, but the Learning Media Assessment goes much further than that to look at the preferred sensory channels of ALL students. The primary reason to perform a Learning Media Assessment is to ensure that all children have access to literacy and to education. In addition, Braille Bills require the determination of literacy media exist at both the Federal and State level. These various Braille bills assume that Braille is the modality to be used unless otherwise demonstrated through appropriate assessment. Learning Media Assessment offers the tool to make that determination and monitor it over time. For instance, the Legislative Changes in IDEA (Individuals with Disabilities Education Act), which was just reauthorized, states the following about Braille: "Consideration of Special Factors: The IEP Team also shall (iii) In the case of a child who is blind or visually impaired, provide for instruction in Braille and the use of Braille unless the IEP Team determines, after a determination of the child's reading and writing skills, needs and appropriate reading and writing media (including an evaluation of the child's future needs for instruction in Braille or the use of Braille), that instruction in Braille or the use of Braille is not appropriate for the child." This means that TVI's have to prove that, at that particular point in time; a student with visual impairments does not need braille. There exists a false assumption that every child who is blind or visually impaired needs braille. A Learning Media Assessment is designed to help TVI's make that determination. Teachers of the Visually Impaired really have to disprove the need for braille. TVI's should therefore be documenting that a child with, for example, cortical visual impairment or severe cerebral palsy, does not need braille, but needs to be evaluated with an LMA and can learn in other ways. The key point here is that TVI's document that their students do not need braille, but that they do need other intervention. LMA's Primary Goals are: "Examine efficiency with which student gathers information from various sensory channels", Types of general learning media the student uses, or will use to accomplish learning tasks, "The literacy media the student will use for reading and writing" and Using the Learning Media Assessment to Guide Educational Planning Once a Learning Media Assessment has been performed, the team should gather to weigh various considerations in order to determine what medium is most appropriate for each student. Some students may learn better through a tactile mode and thus braille may be recommended, while others have sufficient vision to learn to read print. Still others may benefit from dual media, in which they learn both print and braille. For other students auditory channels may be the most appropriate.

A Learning Media Assessment or Reading Media Assessment (LMA/RMA), conducted by the Teacher of Students with Visual Impairments (TVI), is required to determine what kinds of literacy and functional learning materials are appropriate. Although sometimes used interchangeably, the Learning Media Assessment can perhaps best describe the assessment of the learning mode of students who are non-readers or pre-

95 readers. A Reading Media Assessment is a better term for students who are already reading. Either way, it assesses the way a student learns from the environment. The LMA/ RMA is a systematic way of collecting information about sensory preferences, learning environments, and intervention materials and methods. It is used with the Functional Vision Evaluation (FVE) to describe sensory abilities. It identifies sensory preferences, allows the Teacher of Students Visual Impairments (TVI) to understand how to present information to the student. For younger students or those with multiple impairments, the TVI can gain sensory information to the student, understand how to calm or alert the child, and identify adaptations and intervention strategies to promote effective use of senses. In an academic student, it is used to determine the primary or secondary mode for reading or if the student is a dual learner. The LMA/RMA indicates the use of sensory channels; best learning media; indicators of readiness for a literacy program; initial selection of literacy medium; continuing assessment of literacy media; and literacy tools inventory. When conducting the RMA, be sure to provide a variety of environmental print for the student to read in addition to using a formal assessment tool such as the Jerry Johns Basic Reading Inventory. If the student has been prescribed low vision devices, encourage them to use the devices. Possible media includes: class handouts, class textbooks, leisure books, maps, graphs, dictionary, diagrams, ruler, newspaper, magazine, catalogue, ads, phone book, menu, food labels, and clothing tags. Be sure to take note of the estimated font size and type. Also be sure to observe the student's writing skills including keyboarding skills. Include if the student uses the correct fingering, and what the words per minute were as well as the errors. Observe the student copying information from the board and note the distance. Also observe the student copying information from a text to a separate paper. Note the size of writing, the difficulty and note if it was legible to the student and to you. Learning Media Assessment of Students with Visual Impairments identify the following characteristics of students who may be print learners. The student: ●●●●

Uses their vision efficiently to complete tasks at near distances. ●●●● Shows interest in pictures and demonstrates the ability to identify pictures and/or elements within pictures. ●●●● Identifies name in print and/or understands that print has meaning. ●●●● Uses print to accomplish other prerequisite reading skills. ●●●● Has a stable eye condition. ●●●● Has an intact central visual field.

96 ●●●● Shows steady progress in learning to use his/her vision as necessary to assure efficient print reading. ●●●● Is free of additional disabilities that would interfere with progress in a conventional reading program in print.

They identify the following characteristics of students who may be braille learners.

The student: ●●●● Shows preference for exploring the environment tactually. ●●●● Efficiently uses the tactual sense to identify small objects. ●●●● Identifies his/her name in braille and/or understands that braille has meaning. ●●●● Uses braille to accomplish other prerequisite reading skills. ●●●● Has an unstable eye condition or poor prognosis for retaining current level of vision in the near future. ●●●● Has a reduced or non-functional central field to the extent that print reading is expected to

be inefficient. ●●●● Shows steady progress in developing tactual skills necessary for efficient braille reading. ●●●● Is free of additional disabilities that would interfere with progress in a conventional reading program in braille. 2.4

Braille Reading Readiness One of the most difficult tasks facing the kindergarten or first grade teacher is to recognize the degree of readiness to read which her young students have attained by the time they face her on that first September morning. A great deal has been written on the subject of reading readiness, which is as it should be, since it is so important a subject. However, much that has been written is inaccurate, and most of it is incomplete. There is essential agreement on what is meant by the words, "reading readiness." It might be translated as, "the time at which a child is capable of learning to read." Traditionally consider that a child is ready to read when he is about six years and six months old. Formal reading instruction is introduced in kindergarten or in the first grade, and since we have rules that govern when a child may start school, it customarily happens to six-year olds. Thus chronological age is made the official gauge of reading readiness. There are, however,

97 many people who have challenged this timetable. Some parents became aware that their offspring were ready for new experiences and new learning opportunities long before the "average" child was ready. They began trying out new learning experiences on their babies, and they saw that their children not only learned, but that they delighted in the exploration of new territory. Thus was born the belief that children--even infants- were capable of learning far more than had been asked of them heretofore. Educated parents and interested educators became excited with the possibilities of advanced education for very young children, and a new philosophy was instituted; teach your child to read before his second birthday. Babies have been taught to recognize symbols, and they have been taught to match the symbol-clusters with certain verbal stimuli. They have even been able to identify objects symbolized by the printed, written or vocalized stimulus. So far, however, no one has been able to show that a two year old can comprehend, "the blue chair I saw yesterday is softer than the one you are looking at now." There are others who suggest that a child should not be introduced to reading until he is eight years old or older. In any case, in order to decide when reading readiness occurs in a child, we must know what reading is. Is reading the identification of symbols? Is it the ability to reproduce those symbols in some other form, such as pronunciation or cursive writing? Is it the interpretation of the symbols? We can identify and correctly pronounce "slithery in the troves," but can we attach meaning to it? It seems obvious that reading must be "a purposeful activity in which the individual seeks to identify, interpret, and evaluate the ideas and points of view expressed by the writer." The reading readiness process has a number of prerequisites- 1. Before a child actually starts to learn to read, he should have a variety of concrete experiences which give him knowledge about things and relationships between them and also understanding of relationships between cause and effect. 2. A child must acquire basic language skills and sufficient vocabulary to correspond with his experiences. 3. He should be able to understand directions and express himself sufficiently. 4. He should have acquired adequate attention span. 5. He should have developed the ability to localise objects through hearing, a modicum and self -control memory. 6. The child need have motivation and the curiosity to learn about things in general. Reading readiness is the product of the whole child, not a splinter or a segment of

98 himself. Reading is a process of perceiving symbols, of visual, oral and aural discrimination. It involves the ability to form concepts, and it certainly involves prior experience. If a child has never been introduced to the fact of wetness, or hardness, or even of a cow or a cat, the written or oral stimulation of the word will not evoke any mental image in the child. He will not be able to read those words, no matter how well he can pronounce or reproduce them. The time in a child's life when he becomes capable of reading involves a manifold readiness Gestalt. He must have reached readiness in four different aspects of growth; physiological, psychological (emotional and intellectual), educational and sociological (cultural and environmental). A child must be ready physically before he can learn to read. Children ordinarily start out far-sighted, and their eye muscles slowly tighten in their focusing ability. Book publishers are aware of this and accommodate their clients by using large type for little children. Very often we find that poor readers have "double vision" which usually means their focus field is too far out; that they are still farsighted. Also, auditory acuity is a near-necessity. Reading, talking, and listening are so intertwined as to be almost inseparable. There are Helen Keller's in the world, but they are remarkable exceptions. Physical factors are also important in that a child must have mastered at least a modicum of ability in use of fine- as opposed to gross muscular control. The sequence of growth follows a typical pattern in humans, but the rate of this growth is a highly individual process. The sequence of development is from the head downward, from the centre outward, and from gross to refined movements. The grasping of discrimination between "b" and "p" requires fine distinctions, whether the stimulus is visual or oral. A third requirement in physical factors is general good health. If a person has an habitual headache, or he is partially blind, or his feet hurt constantly, he will not be able to concentrate on the intricate process of reading. Psychological factors are every bit as important as the physical, in determining reading readiness. Educators differ in their evaluation of a person's "intelligence quotient," but everyone will undoubtedly agree that there are degrees of mental maturity, and that a child must have attained a certain degree of intellectual functioning before he can assimilate what he reads. One of the most important factors of all is emotional stability and maturity. A child who is at odds with himself and the world will not be able to concentrate on those black-on-white squiggles on a page. A child who has been taught to be super organized and structured will be unable to venture into the excitement of reading and, conversely, the disorganized, wholly impulsive child will be incapacitated. The paranoid child will not be able to accept the authority of the printed word and the autistic child will refuse to respond in any way. The degree of

99 instability or immaturity of a child has a direct relationship to his reading readiness. It is interesting to note that there is a typical pattern of development in the human personality, just as there is in the physical growth. "At some ages (C.A. 2, 5, and 10 years) the child tends to be good tempered, cooperative and well adjusted. These are followed by ages (C.A. 2Y2, 5Y2 to 6, and 11 years) when the child seems at odds with himself and others. There are also regular periods of withdrawal and introspection (C.A. 3Y2, 7, and 13 years) followed by ages at which the child is outgoing, expansive, and adventurous (C.A. 4, 8, and 14 years)." So far as young children are concerned, the third factor, education, must be considered in conjunction with the child's sociological background. Aside from any nursery school he may have attended, educational factors are a product of his family's culture and environment. The type of society the child comes from will have an important bearing on the direction his development takes. Cultural differences have been widely discussed in the past few years and need not be reiterated here. The educational-environmental factor is influenced by the kind of family the child belongs to. Some of the more important aspects are: the language patterns within the home; the concern and interest of the parents in stimulating the child to explore new ideas and new places; the attitudes parents have toward learning, toward school, and toward books; the model they present to the child; and, the care with which they provide mental content, or experiential background. Some of the specific things the teacher hopes a child has learned before he enters first grade, which parents might teach their children, are how to hold crayons or pencils, to become familiar with writing implements, the ability to detect likenesses and differences, the ability to rhyme, being able to interpret pictures, also the conventional left to right progression, and hopefully the attention span of the child will be sufficiently lengthened so he can sit still long enough to learn new things. The teacher who is faced with anywhere from ten to thirty kindergarteners or first- graders cannot expect that they will all be at the same stage in the developmental process. Difficult as it is, it is up to her to recognize the degree of readiness of each of the children. There are many reading readiness tests on the market; however, none of them is comprehensive enough to take into accounting all of the factors necessary. By means of an appropriate selectivity of standardized tests, informal inventories and observation the teacher can become proficient in recognizing the physiological, psychological, educational, and sociological factors which combine to produce the "complete" child who is ready to read.

100 The concept of braille reading readiness depends on three major facts these are as follows- 1. Pre braille training: through pre braille training, the children learn to be sensitive to the positions of the six cells and to distinguish the difference between dots and lines by using Peg Board. When they are ready to teach braille numbers the English alphabet and Bharti braille initial particles. Braille boards are used for practice. Another important aspect in training the 'reading fingers' is the skills of scanning and locating text ranging from the orientation of lines to paragraphs and pages. 2. Tactile training: without vision the children received fragmentary information through their sense of touch and form a concept of the 'whole' from the information of the 'part'. Therefore tactile training and pre braille training are very important to visually impaired children. In order to acquire sensory acuity and efficiency tactile training, manipulative play and art and craft activities are emphasized. 3. Training in Reading Graphics: reading symbolic pictures in raised forms in another specialized area of training since braille textbooks also require the incorporation of graphic illustrations. However when they are in the form of photos they are too complicated to be represented in line graphics and thus brief. The development of tactual exploration and discrimination skills are necessary for future braille readers. It is also important for students with cognitive disabilities who may not be able to learn formal braille, but can learn to discriminate objects by touch to help make sense of their world or to use for communication. Locate & Explore Objects One of the first steps in becoming independent and reaching out to tactually explore the world is for students to attempt to reach out and locate objects. The facilitator may need to assist the student in developing an interest in locating objects. One primary way is to not retrieve objects for the student. If the student loses an object, provide a sound source to help the student locate the object, or touch the object to the student, but encourage them to reach for and obtain the object. This is part of the student beginning to understand object permanence. Encourage students to: ●●●● Reach for and obtain an object that comes into contact with their body. As stated before, try to involve the student in the process of locating and obtaining objects. Students need to understand that objects continue to exist even when they are not 101 in contact.

Tap the toy/object on the tray or floor if it fell on the floor or place the object in touch with the student's arm or leg. ●●●●

Locate partially or fully hidden objects. Help students explore their area and teach them that they can locate partially hidden objects. Play fun hide and seek games by partially hiding the object. If students have difficulty, provide a sound source by the object to help the student locate it. •••• Find objects after systematic search (use a search pattern to locate an object). Teach the student to use a pattern to locate materials. For example, starting in the top left hand corner and working in a zigzag pattern moving to the right and left and up and down until they locate the object. •••• Retrieve object when placed in their usual location. Students should be oriented to the room and be instructed in where materials are kept. Refer to "Labelling System" for suggestions on creating a well-organized area that can assist students in locating materials. •••• Explore a variety of objects with both hands. Provide tactually interesting materials to encourage exploration. The Importance of Tactual Discrimination & Finger Sensitivity When preparing for braille literacy, it is important to develop tactual discrimination skills and finger sensitivity. The development of tactual discrimination skills follows an order from larger to smaller that is similar to the development of the hands and fingers. It begins with using the whole hand to explore objects and progresses to using fingers and fingertips to examine the details of tactile materials. Students with limited sensitivity in their fingers may not be good candidates for braille reading. There are a variety of diagnoses that can cause numbness or reduced sensitivity in the fingers. This will be a factor in determining if a student will be a candidate for formal braille instruction. Tactual discrimination usually follows the following sequence: 1. Three-dimensional forms; 2. Flat shapes, such as puzzle pieces; 3. Embossed shapes with the entire area raised; 4. raised outline shapes and raised lines; 5. and

finally

braille letters.

102 Identify, Compare & Organize Objects Encourage the student to begin to identify, compare and organize objects and toys they are exploring. Talk to the student about different temperatures, weights and textures and encourage them to locate identical or similar materials. Draw the student's attention to where toys and materials are located and encourage them to locate the objects and put them away in their correct place. Encourage students to begin identifying and naming objects. Once they are successfully able to identify objects, begin to transfer this skill to embossed shapes, and then outlined shapes. Developing Tactual Discrimination & Finger Sensitivity You can help the development of tactual discrimination and finger sensitivity by providing many opportunities throughout the day for the student to tactually discriminate materials and compare similarities and differences, classify, and sort. Many commercially produced classroom classification kits consist of moulded plastic figures that all feel the same. These lack the variety of textures of real objects. Instead, use real materials whenever possible. Using real materials that support the current topic make these activities interesting for all students! Draw the student's attention to textures and describe the textures. This will help the student become aware of their differences.

You can help

a student develop finger sensitivity and refine their tactual discrimination skills by providing them with a variety of textures to match, sort and play with and explore. When selecting toys, choose toys that are tactually interesting. Throughout the activities, provide the student with the language that connects the experience.

See the section for a list of materials to classify and sort. Although real materials should always be included in each unit, commercially available texture sorting materials to complement these activities. These activities are as follows: 1. Sensory Play Fill a bin or container with water, beans or sand, or unit related material. Add unit related confetti, sequins, mini bells, beads or other items in colours related to the unit or materials related to the unit. Provide the student with empty containers. Encourage the student to transfer the materials from the bin to the container using sponges in shapes related to the unit or other utensils and tools. Provide droppers, measuring cups, and various tubes for water play. Provide scoops and a variety of tools for dry material play. 2. Texture Match Obtain a variety of textured papers, fabrics, and materials in colours related to the unit. Using the materials, create a texture match board or file folder activity.

103 3. Feely Bag Place unit related items in a bag. Have the student take turns reaching into the bag and identifying the item(s). Once the student has identified the objects, extend the activity by encouraging the student to match the item to the printed word. Encourage the student to have more time exploring the details of the materials. Provide two of each item and have the student match objects. 4. Object/Word Match/Sort Present the student with three identical items or words from the unit and one item that are different. Encourage the student to identify what object or word is different from the others. On the other hand another suggested materials are- (i) Flip-Over Concept Books: This concept book provides interactive, independent learning from young children as they build basic concepts and develop early tactile skills. (ii) Scattered Crowns: Tactile Attribute Game that encourages young children to develop tactile skills. (iii) Ruffs House Teaching Tactile Set: This texture matching toy by directional and positional concept. Learning Resources is another fun way to practice matching texture. (iv) Giant Textured Beads with Pattern Matching Cards: This bead and card set includes 12 large beads that vary in colour, shape, and texture and include pattern matching cards and sorting trays. (v) Occupational Therapy Tactile Discs: This toy challenges children's sense of touch on both hands and feet. The tactile discs are made of synthetic rubber and contain different tactile structures. Activity suggestions for memory and recognition. (vi) Textured Matching Blocks: encourages recognition of textures, identification of textures by name, and actual matching, while reinforcing directional and positional concepts. (vii) Teachable Touchable Textures: These textures by Educational Insights are a fun way to practice matching textures. 2.5 Techniques of Teaching Braille The beginning braille reader, like all beginning readers, must acquire the readiness skills associated with the actual reading process. An important prerequisite that all readers

104 must have to be efficient and read with comprehension is

a rich background of concrete experiences involving many objects, people, places, activities, and cause and effect relationships. In addition, the child must have receptive and expressive vocabulary that corresponds to his experiences. Each individual child must develop auditory skills of identification, closure, sequence, memory for stories, and discrimination. The young reader must be able to concentrate, exert self-control, and follow directions. Another important readiness factor is motivation. Once the student has experiences and language sufficient to read, he can begin a more structured reading program. There are many effective teaching programs used to provide reading instruction. Each child will have his or her own unique set of experiences. The teacher will find that the number and quality of concrete experiences will vary from child to child. One should never assume that basic information is correctly understood until the child can demonstrate that he or she does understand. While both sighted and blind children require language concepts, it is more time consuming to provide the experience required to teach the concepts to the student without vision. Other point is that motivate the child for reading acquired sufficient readiness skills and vocabulary before start meaningful reading. For developing this using various method these are- 1. Word method: the word method makes use of meaningful whole words from the beginning. Children are helped to move their fingers so as to rapidly cover words high interest to them with a single gliding sweep until they become familiar with the total configuration. To encourage discrimination, a sheet of paper may be used, containing three or four words repeated in three or four lines, with the same words being used exactly on the same place in each line. Flash cards can similarly be used and the child be told to sort them on the basis of likenesses. This exercise can be further developed by using words having the same letters or many of the same letters but in different sequences. Analysis of individual letters can be done later on when the child is able to recognise whole word configurations. 2. Sentence method: the sentence method makes use of a few small sentences with varying constructions in which more or less the same words are repeated time and again. The child is first required to memorise the sentences by rote and then tries to read them. The idea here is that with sufficient practice over time, the child becomes familiar with certain words. Analysing of individual letters may not start before the child has learnt to recognise few hundred words. 3. Letter method: in contrast to the above mentioned analytic methods as they are known, we have the synthetic method. Here, the child first learns to recognise

105 individual letters and then combines them into whole words. The first letters may be chosen on the basis of ease of recognition and when the child can tell one from the other with some rapidly; these can be combined together to form words. 4. Multi method: even a multi method approach may suit some children. Here the child is taught to recognise whole words and is simultaneously enable to analyse individual letters. In this metod, letters to form the words may be chosen on the basis of recognition. Remaining letters of alphabet may also be selected according to their ease of recognition. 5. Comparing method: it is different to pronounce judgement on the comparative merits of the four methods of introducing braille. There is perhaps no need for being dogmatic. Children differ from one another in their mental make-up and learning styles. Therefore, different approaches will have to be tried out with each individual child. It is important to provide experiences in a natural environment. The child who has been read to, seen braille labels, and experienced braille books is more apt to understand. The children that have already learned to read print have mastered the "reading process" skills; however, they must develop the skills associated with reading using their fingers. All students learning to use braille must acquire the following: •••• Tactual Discrimination: Theability to discriminate discrete tactualdifferences is essential to efficient braille reading. The noticeable shape orarrangement of dots is the most critical variable in braille reading. Do notteach the child by teaching the dot numbers. This may be helpful to theperson who reads braille with his eyes, but not for the tactile reader. Also, avoid teaching the idea that some letters are reversible pairs? for example, "r" and "w." •••• Finger Dexterity: Theeffective braille reader will have "curious" fingers that move quickly, with ease. Many readers use all four fingers of eachhand. This speeds up the reading process by allowing the reader a view of aseries of symbols rather than a single cell. •••• Hand and Finger Movement: Mostgood braille readers use two hands. A skilled two handed reader begins reading a line of braille by placing bothhands at the beginning of a line. At approximately the middle of the line, theright hand continues to read to the end of the line while the left hand

moves in the opposite direction to locate the beginning of the next line. The righthand finishes reading the first line, 106 the left hand then reads the first words onthe next line, and the right hand quickly joins the left hand on the secondline. •••• Light Finger Touch: Beginningreaders may have a heavy touch, however, to be good two hand readers one must acquire a light touch. Games may becreated to help students develop a light touch. An example of an activity toencourage a light touch is to ask students to slide their fingers across a pieceof paper without moving the paper. This takes practice and attention to task.In addition, the student's hands should move smoothly from left to rightwithout stopping. •••• Page Turning: Thestudent should be instructed to turn the page quicklywith the right hand when the left hand cannot find another line.

As we teach young children with visual impairments/blindness towrite braille, our approach needs to be developmental. We need

to write

braille, our approach

needs to be developmental. We need to look at readiness for formal instruction, and then we need to adjust our pacing, expectations, and activities according to the learning needs of young children. In the guidelines that follow, these approaches are addressed. Before children begin a formal braille writing curriculum, they should be able to attend for at least a few minutes at a time. They also should be able to isolate their fingers and their thumbs, pressing each one separately and firmly. (Modelling with clay and manipulating other art materials can increase hand strength. Children's songs and poems can be used to teach them to isolate and name their fingers. If these are not available, teachers can invent simple verses, themselves.) Next, it would be helpful if the children already have some experience with braille and tactile symbols, pretending to read tactile books and being involved as older children and adults read and write braille. Lastly, because literacy builds upon language, they should be able to speak or sign words and simple messages, and understand as others communicate with them. (However, please note that while language provides readiness for braille, sometimes braille literacy in turn builds spoken/ signed communication skills. In forming braille symbols, children at a prelanguage level may come to realize that written messages carry meaning. This may motivate and shape their spoken/signed language skills.) Make It Fun 1. Emphasize enjoying braille and having fun with it. There is an expression that "play is the work of children." It's important for young children with visual impairments to enjoy reading and writing braille, rather than regarding it as an arduous task that is to be resisted. Adults can make braille fun by incorporating children's ideas in what they read and write, in keeping sessions short, and in

107 modelling their own pleasure in braille literacy. ("Oh, it's a brand new page. The dots are so nice and crispy!" or "I think I'll see how fast I can write the numbers 12345.") Another marvellous way to bring enjoyment to braille writing is to pair it with music, such as singing an alphabet song while writing the ABCs.

2. Give children the opportunity to playfully explore reading and writing. Let them pretend to read as they move their fingers across pages, even if they have no idea what the letters and words say. And let them form patterns and pretend to write before you ask them to produce conventional braille characters. This might involve children simply pressing any keys until they reach the end of a line and the bell rings, or creating an uphill/downhill pattern by pressing dots 3 then 2 then 1 then 4 then 5 then 6, or making a simple tactile graphic by alternating dots 1245 with dots 2356. It might involve pretending to write: pressing seemingly random keys while telling a story orally, just as young sighted children do. Children typically take great pleasure in doing what they notice adults and older children do, and even more when the adult joins them in reading back what they have "written."

3. At the beginning of the curriculum, enthusiastically accept approximations, or all attempts to read and produce braille. Then gradually guide children to use correct posture and hand formation, to read real letters, to decode real words, and to produce Braille which is increasingly closer to conventional braille. A component of incorporating fun into early braille is giving children the freedom to attempt it without needing to adhere to rules they are not developmentally ready for. That is, while some children will be motivated to form correct characters with correct fingering right from the beginning, others will be easily discouraged if every early attempt is suppressed because a key is pressed with the wrong finger, or a character is inverted. As long as correct posture and fingering are expected in a reasonable amount of time, inefficient posture and movement habits don't seem to persist. Given this, a successful practice is to enthusiastically respond to all early attempts to read and write, even when they are incorrect, then gradually expect greater and greater accuracy.

Make It Meaningful

1. Let children experience whole events, from obtaining books or a braille writer and paper, using them, and then putting them away. It clearly takes time for a child to walk to a shelf, pick up a piece of paper and a braille writer, carry these to his/her desk, load the paper in the braille writer, produce his/her work, unload the paper, and pass in the paper and store the braille writer back on the shelf. However, participating in the whole event allows the child to understand the literary process and develop independent literacy habits. The child doesn't need to participate in the full process every time he or she writes. However, it is important for him/her to do this periodically, or at least to participate in some of the obtaining/putting away steps regularly.

2. Let children witness adults reading and writing braille. Fully sighted children regularly see adults as they read books, signs, menus, instructions, etc., and they see them as they write notes, lists, letters, etc. In witnessing adults doing literacy, sighted children learn about literacy tools, literacy techniques, and purposes for literacy. With these models, they become motivated to do literacy themselves. Future braille users need these same models. To accomplish this, even if adults read braille visually and not by touch, they might open their own braille books as they are sitting beside children, explicitly labelling what they are doing. ("I think I'll read this story. Oh, I like how the design on the cover feels. Now I'll turn the page and read who the author is.....") Similarly, adults might make it a point to save some of their braille writing tasks for times when the children are within earshot (and possibly even within reach), so the children can hear a braille writer being carried to the table, the paper being loaded into it, the keys being pressed, lines periodically checked, errors corrected, etc.. The adults may mediate as they write, just as they had when they read out loud, "I think I ought to write down this telephone number, so I won't forget it. Let's see, which dots is a number sign?" or "I'm going to make a list of all the children in the class now. I'll start with a capital sign....." This exposure to purposes and methods of writing will introduce children to some braille writing steps, and it will motivate them to write, as well.

3. Integrate reading and writing, so that children continuously read back what they have written. Braille reading and braille writing are quite separate processes. First, they are based upon different sensory systems. Braille reading is tactile and motoric? dots are felt through the touch receptors in the fingertips as they move across lines. Braille writing is kinaesthetic/proprioceptive and motoric? dots are formed by moving the fingers to press specific keys, and braille writing is mastered by memorizing how the joints in the fingers feel as specific keys are pressed. Secondly, when braille is produced with a braille writer, reading and writing are based upon different layouts of the six dots. Braille is produced in a one-by-six array, with the six keys in a horizontal line to produce, from left to right, dots 321 with the left hand and then dots 456 with the right hand. Braille is read in a

109 twobythreearray: dots 123in the first column, and dots 456in thesecond column. Given these differences, children should integrate reading and writingby writing a few characters, reaching up and feeling what they produced, writing a fewmore characters, feeling these, etc. This sets the stage for more advanced literacyprocesses, where students may write preliminary notes, write a first draft, read it back,then write a finish draft. 4. Approach the mechanics of braille production and reading within the largercontext of Braille literacy. Give children opportunities to produce braille characterswhich are meaningful and functional for them as soon as possible. Children are oftenmotivated to read and write their own names, and those of friends and family members.Children who often ask, "What 's next?" may quickly realize the importance of a simpledaily schedule taped to the corner of their desks. Place a strong focus on reading andwriting messages which have meaning for the children, even when their braille readingand production skills are extremely limited. Make It Developmental 1. Allow some portions of lessons to be child led,that is, let the children have somechoices as to what they write with the brailewriter. This can provide more functionalityand more motivation in braille literacy curricula. For example, in introducing a specificletter of the alphabet, a teacher might let the child select a list of words that begin withthis letter, rather than preplanninga teachermadelist. Similarly, children may be muchmore motivated to read and write lists of family members, favorite toys, or preferredfoods. 2. In sequencing both producing and reading braille characters, build from symmetricalto asymmetrical, from fewer dots to more dots, and from unique characters thatare easily reversed and/or inverted. In addition, in writing braille, try to begin withletters that use the first and second fingers of each hand (dots 1, 2, 4 and 5), thenbuild to writing letters with the third fingers (dots 3 and 6.) (An example of asymmetrical braille letter is "X" and an asymmetrical braille letter is "M." In terms ofnumber of dots, braille letters "A" and "B" have fewer dots with one and two,respectively, while "Q" and "Y" have more with five dots each. "G" is not easilyreversed with other letters, while early readers typically confuse "E" and "I", "M" and "U","R" and "W", and "D", "F", "H" and "J.") Published braille literacy curricula vary in theirsequences of letter introduction. That is, there is not a standard for exactly which letteris introduced first, second, third, etc. However, all the braille literacy curricula for youngchildren take into account these principles

110 of symmetry to asymmetry, fewer to moredots, and unique to easily reversible characters. Beyond that, easilyreversible/invertible characters should not be taught together?for example, a teachermight have the child learn the letter "R" to mastery before introducing the leftrightreversal of "W." Specifically to writing braille, the fingers that are used is also a factorfor sequencing. The first and second fingers of each hand are typically stronger thanthe third fingers, so a braille "A" (dot 1) will probably be easier to form than a capitalsign (dot 6.) Of course, all four of these factors may be trumped by letters/words thatare most motivating and/or most functional for children, such as their own names. 3. Begin by scheduling short lessons, and expect speed and stamina only at theend of the curriculum. Young children have short attention spans, perhaps especiallyfor the more structured, seated tasks of braille literacy.

Physically, it takes time to learn to maintain correct reading and writing posture and hand/finger positioning, to toleratethe sensation of running their fingers over Braille lines, and to strengthen each finger,especially for pressing the keys for dots three and six. It also takes time for children tobuild up speed in reading writing, especially with the letters with more dots.Accordingly, braille writing instruction might begin with just five or ten minute lessonsand expectations of just a few lines of braille. (In braille writing, the margin might evenbe set in the middle of the page, so that each line is shorter.) As lessons progress,lessons become longer and longer and expectations for strength and stamina increase.Sometimes children maintain their attention in braille, and sustain more arm and fingerstrength, when they stand (rather than sit) at a table or desk as they read and writebraille. In any instance, the pages or keys should be at elbow level or even slightlylower. Exercise and special activities are needed to develop strength, dexterity, and endurance. Writing braille using a brailewriter will assist the braille reader by reinforcing his recall and memory of the shape of the letters and symbols. Students will perform better if their hands are clean, dry, and warm. Furniture should fit their bodies allowing the arms from the wrists to the elbows to be even or a bit higher than the desktop. Feet should be flat on the floor and the back straight.

Every braille teacher's "dream student" is the one who approaches the task of learning braille with enthusiasm and an understanding of how much they will benefit from this new skill. In reality, however, many newly blinded adults bring with them a number of myths and stereotypes about blindness in general and braille in particular. Here are some suggestions that may help put braille in a positive light and encourage a somewhat

111 reluctant student to give braille a chance. Change negative attitudes about braille, and dispel the myths and stereotypes. Explain that braille doesn't "make you blind"?nor is being seen reading or writing braille in public a symbol of weakness or lack of ability. On the contrary, knowing braille is a symbol of literacy, competence, and independence. Tell students to bring their literacy skills with them. They already know how to read and write?this is just a new code, and they can learn it. Explain how braille will fit into each individual student's life. Make braille immediately relevant by stressing functional uses: making lists, keeping track of phone numbers and addresses, reading to children or grandchildren, labelling personal items, and so on. Point out that braille will insure privacy. Students can keep journals, write reminders to

them, and

keep track of finances, and so on. Increase positive impressions of blindness and people who are blind. Encouraging students to get in touch with successful blind people is a good way to do this.

students to get in touch with successful blind people are

a good way to do this. Find other adventitiously blind volunteers to mentor newly blinded students learning braille. This way you can set up a "mentoring partnership" with a student and another adult who is blind. People have individual learning styles. Each learner will have his/ her own way of mastering braille and incorporating it into daily life. Here are some suggestions from teachers with experience in teaching braille to adults. Choose the techniques you feel will work most effectively with each individual, and combine them with your own ideas. Start with something simple and personal (e.g., the student's name, phone number, etc.). Building in immediate success encourages the student to continue learning. Use small and familiar motivational items for practice: jokes, Bible verses, quote, and so on. Use a fabricated braille cell to provide examples. Try a muffin tin with tennis balls, an egg carton, a pegboard, or an APH Swing Cell. Teach anticipation. Tell students not to get stuck on a word?skip it and use context cues and letter clues. Use playing cards, Bingo sets, and other games that have been adapted with braille for motivation. Students can continue to enjoy these activities with family and friends, and practice their braille skills at the same time. Motivate students. Cribbage can be motivating, especially since it is a social activity and only uses 4x6 cards. This is a good way to teach numbers. Use braille magazines in areas of high interest (e.g., cooking, sports, etc). Use a Braille 'n Speak and other equipment that has speech to reinforce braille skills. Use flash cards. Cut off a corner for easy orientation. Cut print letters out of heavy paper or cardboard, or use WikkiStix. Then glue them onto the cards. Braille letters

paper or cardboard, or use WikkiStix. Then glue them onto the cards. Braille letters can be made with puff paint, large or small circles made of felt or Velcro, or with a Dymolabeler. Use visual

112 dots to reinforce concepts with learners who can use available vision. Concentrate on the meaning of symbols by making them relevant to daily activities for people with low literacy skills. Make lesson and practice schedules flexible and suited to the needs of individual students (e.g., some may be more alert in the morning, while others may find it easier to learn later in the day). Contract practice time before you start the lesson so that both you and your student are clear on what is to be accomplished between classes. For some students, you may want to suggest several short practice sessions per day rather than one long one. Tape the lessons to help the student remember what he/she has learned. This can also facilitate practicing between lessons. Make homework practical. Assign productive activities that will be functional, as well as good for practicing braille skills. Ask students to try: labelling clothes, canned goods, tapes, CDs, and so on?compiling addresses and family birthdays?labelling medicines and writing out medical information?writing out recipes and directions?making notes from instructions for using adapted equipment?making shopping lists?anddeveloping organizational techniques for home and workplace (e.g., personal files, calendar, etc.). Help clients by assisting in setting up an address book or recipe file using braille so they can add to it as their skills growEncourage family members to participate in reinforcing your students who are developing braille skills by playing games with braille cards, labelling grocery cans after shopping in the grocery store, or keeping track of the weekly shopping list in braille. Give your students lots of support and encouragement.

Research has shown that a few good Braille readers use only one hand, but the vast majority use two hands. The following are typical of the majority of good Braille readers: 1. the student exhibits few regressive hand movements (either vertically or horizontally). 2. Uses very little pressure when touching the Braille dots. 3. Utilizes a two handed reading technique in which the left hand locates the beginning of the next line, while the right hand finishes reading the previous line. 4. uses at least four fingers at all times. 5. Demonstrates the ability to scan efficiently when reading both a vertical and horizontal format. 6. Demonstrates the ability to read letters accurately without confusing letters which are mirror images of other letters. If your student has a heavy touch tries the following: Place a piece of paper on the table, asks the student to pass his hands over the paper so lightly as not to move the paper. Another suggestion would be to place plastic discs or checkers on raised line graph paper and ask the student to pass his hands over the objects so lightly as not to move the objects across the lines on the graph paper. Create your own games which would encourage a light touch. Encourage your student to touch the dots lightly (tickle the

113 dots). Try to help him develop a smooth movement of the hands from left to right and try to avoid having the student stop as he moves across the page. Suggest that your student keep all fingers in contact with the paper. It should be remembered however, that some Braille readers have been known to use unorthodox hand positions efficiently. If your student displays dominant one handed reading, it may take along time to develop the coordination and motivation required for two handed reading. Continue to instruct your student in the two handed method, but respect his right to experiment with other methods when he is working independently. It is important that the school furniture fit the student. The student's elbows should be on the same plane, or perhaps a little higher than the top of the desk or table being used. If the furniture cannot be adjusted, let the student sit on several books (not Braille, of course). Some beginning readers have little strength in their hands or arms. As a result, they may tire quickly. If this is a problem you might try the following activities. 1. Have the student punch holes all the way around a heavy piece of construction paper using a single hole punch. 2. Have the student lace from one hole to another, all the way around the border using medium weight yarn. The resulting product may be used as a placemat during snack time, or folded in the middle and used as a cover for completed work. 3. As a reinforce for work completed satisfactorily let the student use a nutcracker to crack nuts, after which he may eat them. Start with peanuts first. 4. Cut strips of heavy construction paper (about 1/2" wide). Have the student cut across the strips with scissors to make pieces of paper. The small pieces may be pasted down to decorate the folders. 5. A box containing several dozen nuts and bolts of the same size may be given to the student to put together. Clean warm hands are important for rapid and correct Braille reading. Be certain that your student washes his hands, rinses them thoroughly, and uses a little hand lotion before beginning to read. An old hair dryer is useful on cold days to warm hands before reading. Place the student's worksheets one at a time on top of a rubber pad. This prevents the paper from slipping around the desk and thereby, promotes a light reading touch. This is a consumable program. That is, an entire new set of Braille work sheets should be provided for each student who receives instruction through this method. The pages

114 should be taken out of the binders and used according to the instructions in the teacher's manual. The use of the pushpins will deface the pages, but will strengthen the arm muscles and heighten the reading performance of the student. After use, the pages should be given to the students to take home. Sighted children take home completed pages every day and proudly boast to friends and family about their marvellous achievements. Visually impaired students need the same kind of reinforcement and encouragement if they are to maintain enthusiasm toward reading. Teachers will doubtlessly be tempted to keep the entire program and use it with other students. Braille becomes rubbed down easily when used with beginners. Every student deserves an equal opportunity. Many adults think of Braille letters as reversible pairs. i.e., (w and r) etc. Never, teach a child that there are reversible pairs of letters in Braille. This requires that the student perform a double mental process when he applies his knowledge of letters to academic assignments. Remember that one of your greatest strengths is your ability to reinforce correct reading techniques. Reinforcing incorrect techniques only shows the student what is "bad", but offers no example of the desired behaviour and thereby, provides no substitute for the "bad" techniques. Reinforcing correct techniques provides an example of the goal behaviour and increases the probability that the desired behaviour will recur more frequently. Good reading skills are only mastered after years of practice. 2.6

Techniques of Teaching Print to Children with Low Vision Approximately 90% of individuals with visual impairments have functional or

low vision? Just 10% are functionally blind. However, students with low vision are often an overlooked majority in the population of children who are visually impaired. Difficulties of students with low vision are often not as apparent as they are for students who are blind. Nonetheless, students with low vision require direct instruction in literacy, visual efficiency, accessing the core curriculum, compensatory skills and more.

The following educational interventions are beneficial to students in any school setting: Teacher of Students with Visual Impairments Every child who meets the criteria of visual impairment in his/her state is eligible to receive services from a certified teacher of students with visual impairments (TVI). A

TVI is a teacher who specializes in working with students who are visually impaired. Most often, when a new student with a visual impairment enters a school system, it is the TVI who is responsible for assessing the student, determining and aiding in adaptations and modifications, as well as creating individualized education programs

115 (IEPs). If the situation does not permit the TVI to perform all necessary specialized instruction with a student, the TVI will generally oversee or direct the instructional process.

Accessing the Visual Environment

One of the principal concerns for students with low vision is their ability to access the visual environment.

Just as students who are blind have difficulty with environmental cues such as facial expressions and eye contact, so too do students with low vision. One way for students to access the visual environment is through optical devices. Optical devices include magnifiers, microscopes, and tele-microscopes for accessing near information and monocular telescopes and bioptic lenses for accessing distance information. Near devices aid a child in viewing regular print materials, non-textbook materials such as baseball cards, and menus. Distance devices are used for viewing information that is beyond arms reach, such as the chalkboard, menus in fast food restaurants, or sporting events. Because every child's vision is different, a certified professional should always prescribe optical devices. Every child with low vision should receive a clinical low vision evaluation from an optometrist or ophthalmologist who specializes in such services.

Access to information One of the most important academic areas related to accessing the visual environment is accessing information through print. While some students with low vision require their texts to be transcribed into braille, many are able to access regular or large print. Large print books and papers can be created through modern copy machines but such copies are often of poor quality. Many states have centres and agencies that can be contracted to create required large print and braille materials. For students who can access regular print through optical devices, instruction beyond the introduction of the optical device is required to make sure the student uses it effectively. Lengthy texts such as novels might also be presented on audiotape. However, it is recommended that audiotape materials not be stressed until later grades to ensure that students develop the requisite basic literacy skills. Audiotapes are often used more by students in university who must access large amounts of information from a variety of sources. Many technology solutions exist for accessing information via computer. Progress is being made on the ability to download academic texts from publishers directly to student's computers, bypassing the print medium. Text on computer can be output through speech,

116 large print, or braille, depends on the software and hardware available. Some students might also benefit from any combination of braille, large print, regular print, optical devices, and technology.

Access to core curriculum Students with low vision are often at a disadvantage when presented with information in regular classrooms. If a student has difficulty seeing material at a distance, writing on chalkboards will be hard to discern. A distance optical device, preferential seating, and hand-outs containing pertinent information are all ways that the information can be more easily accessed by the student. Curriculum areas such as the sciences that require hands on activity and interaction with materials can also present a challenge to students with low vision. Specialized instruments with larger numbers or inventive ways of using existing materials can overcome barriers. The use of groups to complete assignments is also useful for providing a support not only for students with visual impairments but for all students. Above all, teachers should encourage students to indicate when they are having difficulty in accessing information, completing a task, or understanding a process or skill. In most cases, between the student and the teacher for students with visual impairments and the classroom teacher a solution for any barrier will be discovered. Psychosocial Issue Another issue relating to low vision is the psychosocial impact of a visual impairment. Children growing up with a visual impairment can experience many negative consequences including: feeling like they look different, either because they cannot visually verify how others look or because they wear glasses or use optical devices, feeling like an outsider because they cannot take part fully in activities, feeling less than capable because they do not understand visual concepts fully, feeling clumsy because they drop things or bump into objects. All of these consequences can have the effect of lowering self-esteem. It is important those students identify themselves not by their visual impairment but see their visual impairment as one aspect of who they are. Intervention may be necessary so that a student can build successful experiences and find activities in which they excel. Unique educational interventions are essential for students with low vision in order to ensure successful outcomes in the school setting. For educational purposes, the low vision student is typically one who reads print and has a corrected visual acuity of 20/70 or worse in the better eye. Most low vision students

117 have very poor distance vision, so this makes it difficult for them to see the chalkboard or to gather detailed information from filmstrips, charts, or overhead screens. These students can usually read print and gain information from pictures, charts, and graphs when the material is up close. Each low vision student's needs are unique, but the following suggestions may be helpful when working with a low vision student in the classroom. Some General Facts Regarding Students with Low Vision: •••• Using the eyes does not injure or harm them. Encourage the student to use his/her eyes since greater efficiency can only be developed through the use of the eyes for visual tasks unless a doctor has indicated otherwise. •••• The use of glasses cannot help improve visual acuity for all eye conditions. Glasses may be worn to reduce glare and help with fatigue. Some students can read ordinary type with ease?others may require large print, a hand-held magnifier, or a closed circuit TV. The visually impaired child should be able to participate in most recreational activities except for those that require good visual acuity. •••• Eyes cannot be "strained" but may tire quickly. An activity that allows the student to change focus is often helpful and appreciated. •••• Holding materials close to the eyes will not harm them. Allow the student to position materials at a distance he/she chooses. •••• Check the student's folder for the modification sheet. This will tell the classroom teacher what specific modifications need to be made in the classroom. Remember, these modifications are REQUIRED, since they are written in the student's Individualized Education Plan (IEP). Contact the teacher of the visually impaired if have questions or need suggestions for particular room.

Suggestions for the Classroom Teacher: •••• Preferential seating is often necessary for a student with low vision. •••• Let the student select a seat where he/she sees best •••• Seat a student as close to the board as practical •••• Reduce glare from windows and lights, as much as possible •••• Seat the student with his/her back to windows •••• Read the student's Functional Vision Evaluation to find out if this student can copy materials written on the board or overhead projector.

118 ••••

Purple dittos or "fuzzy" Xerox copies should not be used with this student.

Clear contrast between the print and the background will help the student be more successful. •••• Black print on white paper is usually best. If other modifications are required they should be contained in the list of modifications handed out at the beginning of the semester and in his/her Functional Vision Evaluation of the Special Education Folder. •••• Contrast, print style, and spacing of letters can be more important than print size. •••• Low vision students may require more time to complete assignment. •••• Low vision students are usually slow readers because of the visual impairment. •••• Standardized tests that require separate answer sheets may be especially difficult for a student to use. Check modifications to see what procedure to use. •••• Word games, puzzles and graphs may be inappropriate for a low vision student. Check with the VI teacher if unsure. •••• Give the student the grade he/she earns. Donating a grade to a student really hinders-not helps the student's learning. •••• Storing and using large print materials may be difficult for the student to manage in a classroom. Help the student find a place for books and supplies. Also, a locker may not be accessible if it has a combination lock.

Understanding A Low Vision Student: •••• The emotional needs of a low vision student are like those of any other. He/She wants to be liked by teachers and peers. They do not want to be different. •••• Schedule a time for a private meeting with the child. This will allow the student to tell you about seating preferences, lighting, and modifications that are helpful. •••• Have the student explain his/her visual problem to you. •••• Try not to call attention to the child's eye problem in front of the class. •••• Always use the student's name when addressing him/her. •••• The rules of discipline should be the same for a low vision student, as for any other, unless the IEP states otherwise.

119 •••• So much of communication is non-verbal. Often a student with low vision is unable to recognize the expression on someone's face or figure out what has happened in a situation that is nonverbal. It is helpful if the teacher privately explains the situation to the student with low vision. •••• Be aware of the student's frustration level since so much of learning and school is visual. It is easy for a student with poor acuity to become frustrated. •••• If notice the student has food or ink on his face or clothes, discretely tell them. A Functional Vision Assessment and Learning Media Assessment should be done for each student, and these generally offer specific suggestions for optimal visual functioning, including magnification, lighting, font size, colour preference, and ideal environmental conditions. The individual needs of a student will depend on factors such as his or her eye condition, age, learning style, and additional learning challenges. Strategies for Reading Print There are a variety of ways in which students with low vision can access print, and many students will use different strategies in different situations. For example, out in the community, they may prefer to use spot magnification to check menus or prices, but in school they may prefer to use text books in large print. A CCTV (Close Circuit Television) or other form of video magnification may be the preferred way to view graphics or a text in school that is not available in large print. It is often necessary for the student to try different tools in various circumstances in order to be part of the decision making process about what works best. SETBC (Special Education Technology British Columbia), a provincial resource program of the BC Ministry of Education, outlines strategies for paper materials, as well as e-text. Instructional strategies for paper materials include: 1. Provide regular print 2. Use handheld magnification with regular text 3. Enlarge Small Amounts of Text, Pictures, Diagrams, Charts on Photocopier 4. Provide Large Print Version of the Text 5. Use Standalone Video Magnification 6. Use Video Magnification with Computer Integration Additional strategies for e-text include: 1. Change Appearance of Text and/or Background

120 2. Magnify Text and/or Computer Screen 3. Provide E-text with Tracking Support or Highlighting 4. Provide E-text Environmental Factors The Functional Vision Assessment will include specific strategies and suggestions for the individual student, based upon his or her visual condition, the type of educational program, the child's age, and other challenges the student may face. The needs of each student will be different depending on the eye condition, but in general it is necessary to consider the following: 1. Glare 2. Contrast 3. Lighting 4. Positioning 5. Reducing Visual Clutter 6. Visual Cues 7. Self-Advocacy Font When determining which font to use, it is important to look at both the size and the type of font. APHont: A Font for Low Vision (American Printing House for the Blind) APHont was developed by APH specifically for low vision readers. APHont embodies characteristics that have been shown to enhance reading speed, comprehension, and comfort for large print users. 2.7

Braille Aids and Devices, Optical Devices for Print Reading and Writing

Braille Aids and

Devices Students who read braille also usually write in braille, using a variety of low or high-tech devices. If your child writes in braille on a computer or personal digital assistant (PDA), the teacher of students with visual impairments can use braille translation software, which converts the text and prints it out for you, the teacher, or anyone else

121 who reads print. There are a number of different methods for personal braille writing that can result in tactile output. The focus here is on the process of writing braille which assumes, of course, that one either knows or is copying correct braille in the first place. (Note that while writing braille can be used for transcribing from print to braille, it is not the same as transcribing. Different writing methods have different advantages and many braille lists end up using different ones depending on their purpose. On this page I've made a distinction between mechanical and electronic devices. Another distinction, which is more significant to braille literacy, is between brailers and note-takers. Brailer is the name generally given to a device with the capability for direct output of embossed braille whereas a note-taker is a device that has digital storage capabilities and, possibly, direct output via a speech synthesizer or refreshable braille display (RBD). Tactile braille can be produced by sending an electronic braille file produced using a note-taker or personal computer to an embosser (or RBD) just as ink print can be produced by sending an electronic print file to an inkjet printer. (However, even a low end embosser is considerably more expensive than an ordinary printer.)

Writing and braille literacy The writing devices most significant for early braille literacy are those that like pencil and paper couple writing and reading by tying the writing process directly to the production of hard copy output. These devices include the slate and stylus as well as mechanical and electronic brailer. Attempting to achieve braille literacy by restricting oneself to the use of a speech enabled braille note-taker would be rather like attempting print literacy with a computer keyboard and a word processor with synthetic speech output. Braille writing devices like the slate and stylus and brailer are also uniquely important for blind children because they allow a blind child to develop the two dimensional or planar concepts that a sighted child picks up automatically from seeing a page. The child develops an understanding of writing on a page, page size, formatting, alignment, information on a page, etc. that is not possible with virtual writing. On the basis of this the braille devices can be further

classified into the following broad six categories: 1.1

Braille Duplicators and Writers 1.2 Writing Devices 1.3 Braille Paper 1.4 Talking Books and Tape Recorders 1.5 Reading Machines 1.6 Braille Computers

122 1.1 Braille Duplicators and Writers •••• Thermoform Machine: '

Endotherm'

is an indigenous

semi-automatic Braille duplicating

machine. It is useful for taking out multiple copies of the Braille matter on the Endotherm (or Braillon) sheets from the master generally prepared on the Braille paper. This machine operates on the principle of vacuum and high temperature.

••••

Braille Writers: It

is an upward writing machine for writing on one side of the paper, enabling the Braille

to be read as it is written. This machine can be compared to a normal type writer with a major difference that it has only nine keys, three for paper setting and six for embossing; the brailer embosses combinations of six dots in a Braille cell.

The

Braille machine

is made of metal with an enamel finish, with plastic key-tops and adjustable margin stops. The paper is roller-fed and line spacing is achieved by pressing a

special key. 1.2 Writing Devices •••• Peg Slate: This paperless device helps to teach beginning users of the braille slate. A frame is mounted with pegs that represent the braille dots in 10 braille cells. A finger is used to push the pegs down. The frame is then flipped over to read the braille message. Made of black plastic with white plastic pegs for high contrast. Instructions in print and braille. •••• Slate and Stylus: The slate and stylus are inexpensive, portable tools used to write braille—just the way paper and pencil are used for writing print. The most low tech method of writing braille, comparable to writing print with pen or pencil, is to emboss each braille dot using a stylus and slate. This method ordinarily requires writing from right to left. (One can also write from left to right by writing upside down but this is generally more error prone.) Slates are made of two flat pieces of metal or plastic held together by a hinge at one end. The slate opens up

to hold paper. The top part has rows of openings that are the same shape and size as a braille cell. 123 The back part has rows of indentations in the size and shape of braille cells. The stylus is a pointed piece of metal with a plastic or wooden handle. The stylus is used to punch or emboss the braille dots onto the paper held in the slate. The indentations in the slate prevent the stylus from punching a hole in the paper when the dots are embossed. Slates and styluses come in many shapes and sizes. ••••

123 The back part has rows of indentations in the size and shape of braille cells. The stylus is a pointed piece of metal with a plastic or wooden handle. The stylus is used to punch or emboss the braille dots onto the paper held in the slate. The indentations in the slate prevent the stylus from punching a hole in the paper when the dots are embossed. Slates and styluses come in many shapes and sizes. ••••

Interline Braille

Frame: is used for writing standard character interline Braille. The frame comprises a woodenboard, a metal guide, a reversible paper clamp and astylus. The clamp fits at the top of the board and has a small swivel stud for locking and holding Braille paper. When one side of the paper has been Brailled, the clamp with the paper still held, is turned over as a unit. The binding margin is made automatically. ●●●●

Taylor Postcard

Frame: It

is used for writing small character Braille on one side of the paper. The corner pins are arranged in such a way that the Braille can be read

124 without removing the paper from the frame; when the top section is lifted, the paper remains attached to it. ●●●●

Pocket Braille Frame:

The

four-line pocket Braille frame produces small character Braille on one

side of the Braille paper. This is specially used for making small and occasional notes. ●●●● Styli:

These

are produced with handles of various shapes

to suit individual needs. The points of all styli are made of stainless steel and the handles are of polished hardwood or synthetic material. ●●●●

Braille Kit: is a

retine coated or a decorative wood box and

contains the following items: ✓✓✓✓ Braille Writing Frame ✓✓✓✓ Braille Writing Pocket Frame ✓✓✓✓

Rubber Sheet ✓✓✓✓ Foot Ruler ✓✓✓✓ Compass Set ✓✓✓✓ Two Styli ✓✓✓✓ Folding Stick or Abacus and ✓✓✓✓

Signature Guide. ●●●●

Pragnya Sketching Device: It enables a visually impaired child as well as a low vision child

to create simple sketches and diagrams out of a thread. It is based on principle of using acrylic thread as "writing ink" and nylon fabric fastener strips as a "writing slate".

125 ●●●●

Product Design: Acrylic thread of a contrast colour that works as refill is passed through the empty body of an open ended ball pen, keeping the other end attached to bobbin spool. The thread is wound on the spool that rotates about a wire axle, attached to the upper part of the ball pen. The nylon fastener strips are stitched together width wise and pasted on the woodenboard to make 1'x1' area. ●●●● Operation: The child holds the pen as any other normal pen for a sighted person and makes contact of the thread over the slate surface. Keeping continuous touch with the surface, the child glides the pen in different directions and the thread delivery is maintained smoothly through the rotating spool. A line can be terminated by snapping off the thread by using a sharp stationary blade. A continuous running thread can also make different shapes like circles, rectangles, curved lines, letters, graphic symbols, maps etc. The drawn picture can be easily "erased" by simply pulling away the thread from the slate surface and rewinding it again over the spool. The child can immediately feel the shape by moving fingers over the thread surface and add, correct or erase the line quickly. It enables interaction of the child with the writing media and encourages drawing of various objects. A low vision child may see the shapes by holding the board close to eyes. Advantages (i) Self operated excellent user friendly device (ii) Serves as useful educational media for the teaching personnel (iii) Operates on concept of "draw as you think" which is better as compared to tactile devices where "embossing" is carried out on the reverse side of the paper, metal sheet etc. to get mirror image of the actual profile. (iv) Simple design using readily available components. (v) Easy to manufacture, even in the rural areas. (vi) Low cost and affordable. (vii) No training manual required as it is easy to operate. ●●●●

Braillewriters: Mechanical embossers that support six key entry are usually called brailleur? Mechanical braillewriters work a little bit like typewriters. They have six keys-one for each dot in a braille cell-a space bar, a backspace key, a carriage return, and a line feed key. Braillewriters use heavyweight paper. The most popular braillewriter is the Perkins braillewriter, made by the Perkins School for the Blind in Massachusetts. One high-tech device devoted to writing in print is the

126 Mountbatten Braille. The Mountbatten Braille combines a mechanical braillewriter and computer in one device. It has the same keys as a braillewriter, but the keys do not require as much pressure to operate. As your child uses the Mountbatten, she can feel the braille paper to see what she has written. The Mountbatten has computer technology built into it so that files can be stored and retrieved at a later time, and the device can also "speak" aloud what is Brailled. The Mountbatten is typically used with younger children or with children who have additional disabilities and limited hand strength. A new design for a mechanical six-key braille has recently been developed by an Australian researcher after many years of effort. This new device is known as a Jot A Dot and is currently expected to be commercially available in January 2003. It looks much like an electronic braille note-taker.

127 1.3 Braille Paper:

The standard size of Braille paper is 22"x28" and weight 8.6 kg. per gross. 1.4 Talking Books and Tape Recorders •••••

Talking Books:

The material recorded on cassettes has emerged to be the most popular mode of imparting education to visually impaired persons. As Braille books are very heavy and many newly blind persons are not able to learn Braille easily, talking books are emerging to be the most viable alternative.

For listening to the talking books, the conventional cassette players with the compact cassettes with a playing time of either 60 or 90 minutes are generally used. •••••

Digital Tapeless Recorder: The blind people can use it alone without someone's help.

It has a special voice prompt for the blind which includes a voice guide, easy research mode, volume adjustment and option for use of earphone. 1.5

Reading Machines ••••• Kurzweil Reading Machine:

A portable optical scanner that reads type-set or type-written text and turns it into speech.

Its features include: (i) a large memory to provide improved processing of incoming text; (ii) an automatic contrast control; (iii)

tools for format analysis; (iv) multi-lingual capability for text in any of these verbal languages; (v) communication interface which allows it to serve as an input or output device with other data or text processing equipment. ••••• Optacon: is

a book-sized electronic device with a movable camera, the size of a pocket knife and a tactile screen the size of a fingertip which presents a tactile image on an array of vibratory pins. The reader passes the camera over printed material with his right hand and his left index finger feels in vibratory relief the image the camera sees. The manufacturer claims that an experienced Optacon user reads up to 90 words per minute, about half his Braille reading speed. 1.6

Braille Computers ••••• Braille Window: is the Braille-display for connection to all sort of IBM compatible personal computers.

128 ••••• Keytone: is a portable information handling, word processor and computer access device that talks to its user.

••••• EHG-BW/ 2-PIEZO: is a monitor and key board which provides output in raised dots and can be conveniently used by the

visually impaired persons. ••••• Galaxy Piezo: is a special computer for the visually impaired and it gives output in

embossed dots. ••••• Galaxy speech: is a special computer for the visually impaired with speech output ••••• Braille'n

Speak: is pocket size note taker. It can be used for word processing, as a calculator, as a clock and a calendar. It can store 200 pages of Braille text. •••••

Versa-Braille II+: is recognized as a convenient Braille operating system. It can be used for editing, programming and word processing.

The input is from six keys and output is in the form of raised dots. It is a product of Tele-sensory Systems Inc. •••• Index Braille: Index Braille is a Sweden based privately owned business with a mission devoted to development and production of Braille Embosser. The company has introduced Double-sided Braille Embosser, popularly known as "Index Everest". It has a high speed Interpoint Braille Embosser which uses normal cut sheet. Over the years, the Everest has proved to be one of the most reliable Embossers on the market. ••••

Speech Synthesizers: A speech access system converts text from a computer into spoken words. It is the hardware device that does the speaking in a speech access system.

Important features of synthesizers include (i) voice quality (ii) speed at which text is converted to speech (iii) memory requirements, and (iv)

compatibility of the synthesizer to the computer (Mac or PC) and the number of languages available.

a. External device: It connects to a computer externally and comes with a speaker and a socket for headphones and can be moved around to different machines.

129 b. Internal device: It comes as a chip or a circuit

board that must be inserted inside the computer with sockets for speakers and headphones. It can be moved around to different machines, it works faster than an external device. c. Soft-ware based device: It is loaded as software on a compatible computer and it gives speech out through the sound system of the computer itself. The Microsoft Voice is useful for reading the documents and for operating window commands with the help of multimedia kit.

d. Language software: The Indian Institute of Technology (IIT) Chennai has developed Braille Software as well as Language Software which enables a visually impaired person to access computers for Braille as well as language outputs in all the Indian languages.

It is also providing the software completely free of cost to the users and the

institutions. It has also developed a system of keyboard mapping and operations in Indian languages and instruction manual for use of the special version of the ITI

Multilingual Software. e. Refreshable braille display: A refreshable braille display or braille terminal is an electromechanical device for displaying braille characters, usually by means of round tipped pins raised through holes in a flat surface. Blind computer users who cannot use a computer monitor can use it to read text output. Speech synthesizers are also commonly used for the same task, and a blind user may switch between the two systems or use both at the same time depending on circumstances. Deaf blind computer users may also use refreshable braille displays. The base of a refreshable braille display is a pure braille keyboard. There, the input is performed by two sets of three keys plus a space bar (as in the Perkins Braille), while output is via a refreshable braille display consisting of a row of electromechanical character cells, each of which can raise or lower a combination of six (or in some cases, eight) round tipped pins. Other variants exist that use a conventional QWERTY keyboard for input and braille pins for output, as well as input only and output only devices. On some models the position of the cursor is represented by vibrating the dots, and some models have a switch associated with each cell to move the cursor to that cell directly. The mechanism which raises the dots uses the piezo effect of some crystals, whereby they expand when a voltage is applied to them. Such a crystal is connected to a lever, which in turn raises the dot. There has to be a crystal for each dot of the display, i.e. eight per character. Because of the complexity of producing a reliable display that will cope with

130 daily wear and tear, these displays are expensive. Usually, only 40 or 80 braille cells are displayed. Models with between 18 and 40 cells exist in some note-taker devices. The software that controls the display is called a screen reader. It gathers the content of the screen from the operating system converts it into braille characters and sends it to the display. Screen readers for graphical operating systems are especially complex, because graphical elements like windows or slide bars have to be interpreted and described in text form. Modern operating systems usually have an Application Programming Interface to help screen readers obtain this information, such as UI Automation (UIA) for Microsoft Windows, VoiceOver for OS X and iOS, and AT-SPI for GNOME. Optical Devices for Print Reading and Writing An estimated 1 in 250 children are visually impaired as a result of eye disease. Some of these children have nearly normal vision, some are totally blind, but the majority fall into a broad range between these two points. Children are said to have 'low vision' or 'partial sight' when they have: (a) a corrected visual acuity in the better eye of $\geq 6/18$ to 'perception of light' (or a visual field of less than 10 degrees) and (b) the ability to use their residual vision to orientate themselves or to perform tasks. They are identified at eye clinics, school screening programmes, community based rehabilitation (CBR) programmes or special schools for the visually impaired. The education, employment prospects, independence and quality of life of a child with low vision can all be improved by enhancing vision. Optical devices (spectacles, magnifiers and telescopes) play a key role in achieving that approximately half of children who have low vision show an improvement in distance and/or near visual acuity with the help of spectacles, a magnifier or both. The majority of magnifiers are prescribed for children who have a visual acuity in the better eye of $\geq 6/60$ to $1/60$. The management of children with low vision requires cooperation between the child, his/her family and eye care educational and social personnel. There are five stages in the management of children with low vision. Eye care personnel are primarily involved in the assessment and monitoring stages which include: visual acuity measurement (distance and near) eye examination, diagnosis and prognosis surgical and/or medical treatment and the provision of optical services. Sight is a key source of stimulus during a child's development, and so children with low vision should be motivated to make the maximum use of their residual vision. This can be done using both non-optical and optical methods. Large Print Standard print is usually in a 10-12 point size. While large print was often thought of as 18-24 point, today computers and printers can produce text in any size the user desires and in a variety of fonts. Most users of large print prefer a sans serif font such as Arial or Verdana which do not have embellishments on letters that can cause visual clutter and confusion like those found on Times New Roman and other serif fonts. Non-optical Devices Tools that do not optically magnify or change the image being viewed. Lighting options-appropriate lighting conditions can greatly improve one's ability to read printed information. Natural-natural lighting is a great source of lighting for reading especially when it can be controlled with blinds, shades, or curtains. Book/reading stands-allows the reader to place reading materials at a comfortable position for reading and are available in portable, desktop and floor models. Light filtration systems-better known as sunglasses or colour filters, these devices can be very useful especially in brightly lit environments. Enhancing Vision Using Non-Optical Methods •••• Move CLOSER, e.g., use an angled reading desk. •••• Use COLOUR to show objects more clearly. •••• Use CONTRAST, e.g., eat white rice off a coloured plate.

132 ●●●● Pay attention to LIGHTING, e.g., sit near a window in class. ●●●● Make objects LARGER, e.g., write with larger letters. ●●●● Use a LINEGUIDE such as a ruler when reading and writing. ●●●● Optical Devices. These devices magnify the image of the material being viewed and should be prescribed by an eye care professional specializing in low vision. The most widely used optical devices are spectacles or eye glasses and contact lenses. When these do not provide enough magnification users can turn to handheld or stand magnifiers. Enhancing Vision Using Optical Devices Optical devices play a key role in enhancing vision and reducing visual disability in children with low vision. They include: standard prescription spectacles?optical low vision devices for distance vision?and optical low vision devices for near vision. a. Standard prescription spectacles: It is important to ensure that children with low vision are refracted and provided with any spectacles they require. Work in West Africa indicates that at least 30% of children with low vision needs spectacles. Refraction should always be carried out before a magnification assessment. b. Optical low vision devices for distance vision: Distance vision magnification requires a telescopic lens system. Telescopes are expensive and have limited applications. It is often more practical for a child to sit near the front of class to see the backboard than to use a telescope. c. Optical low vision devices for near vision: An optical low vision device for near vision uses one or more lenses placed between the eye and an object to alter the retinal image size of the object. This makes the object larger and easier to see. The minimum dioptric power of a device used in this way is +4.00D. These devices are inexpensive and have a wide range of applications. They play a vital role in giving children with low vision access to print and illustrations in standard textbooks. Prescribing Magnifiers for Near Vision The power of magnifier prescribed for a child is determined by the child's visual requirements, recorded near visual acuity and measured working distance. They are prescribed, starting with low power magnifiers and then progressing to higher powers. The higher the power, the smaller the area of visual field seen through the magnifier. More

133 words in a sentence can be viewed through a +10D magnifier than through a +20D magnifier. The power of the magnifier prescribed should be the maximum power which enables the child to perform the task required, but not above requirements so that maximum visual field is maintained. Moving the eye closer to the lens of a handheld or stand magnifier also increases the field of view. In West Africa 71% of magnifiers prescribed were low power magnifiers (under +25D). These were prescribed more frequently for those with a visual acuity of 3/60 or better. High power magnifiers (over +25D) were prescribed in 29% of cases and were mainly prescribed for those with a visual acuity of less than 3/60. To determine the appropriate type of magnifier it is important to assess the child's personality, coordination, motivation and task aims. The same magnification can be provided using different mounting systems and working distances. Optical devices for near vision include: handheld magnifiers (illuminated or non-illuminated) ?stand magnifiers (illuminated or non-illuminated) ?spectacle mounted magnifiers (e.g., high plus spectacle lenses, Hyperocular lenses)?and spectacle mounted telescopic units. The most widely available optical low vision devices for near vision are non-illuminated handheld magnifiers, non-illuminated stand magnifiers, and high plus spectacle lenses. There are many benefits in providing magnifiers to children with low vision. The magnifiers encourage children to use their low vision to the full, thereby increasing visual stimulus and helping the children's development. The magnifiers promote literacy by increasing access to printed material for educational purposes and private reading. It is also more cost effective to provide children with optical devices enabling them to use standard books than to provide large print books which are expensive and heavy to carry. There are some limitations in providing magnifiers. Using a magnifier may make a child's visual disability more noticeable causing the child to feel different from other children. The human and financial resources available to provide the magnifiers may be limited. The child needs to be taught carefully how to use the magnifier as the restricted field of view can prevent a child from perceiving the overall pattern of words or sentences on a page.

Optical devices are of two kinds near and distance. Near devices are designed for magnifying close objects and print. Distance devices are for magnifying things in the distance (from about 3 metres to far away).

Check that each person has been examined to see if spectacles are needed to correct or improve vision before recommending low vision devices. It is necessary to find out what people are unable to see and what they want to be able to see well. It might be a very specific task such as reading labels on food packets. The nature of the task will also affect the type of low vision device which

134 is suitable. Before selecting a low vision device, consider: ••••• the size of objects to be viewed ••••• the possible viewing distance from the object ••••• the length of time needed for the activity ••••• whether one or both hands are needed for the activity. ••••• Some people use both near and distance devices, others use only one type. Optical devices for near tasks Magnifiers for close tasks are designed to be either held in the hand (handheld magnifier), to be placed on a book or over a small object (stand magnifier) or mounted in spectacle frames. With magnifiers for near tasks, objects or print look larger and detail can be seen. A standmagnifier is a strong lens which is mounted in a plastic stand. A stand magnifier is usually easier than a hand held magnifier for a child to use. It can be moved along while still resting on a page of a book. With spectacle magnifiers, both hands are free to work on tasks. Magnifiers for near tasks can be used for: ••••• reading a book or a newspaper ••••• reading labels, signs or prices in shops ••••• using tools, for example measuring ••••• threading a needle ••••• identifying money ••••• inspecting objects such as plants or insects

135 For reading, the magnifier has to be moved along each line of print, sometimes only showing a word or part of a word at a time. More words will be seen if the eye is held close to the magnifier. Reading is very slow at first. It is difficult to learn to use the magnifier properly a lot of practice is needed. Optical devices for distance tasks Magnifiers for distance are like small telescopes. They improve the ability to see distant objects or people. Objects appear to be closer and it is hard to judge distances properly. It is best not to use telescopes while walking around. Training to use optical devices Encouragement and training are needed for people to use low vision devices well. The field of view or amount able to be seen through the magnifier or telescope is small. It takes practice to be able to find objects and then follow them or scan to find other objects. For distance tasks it is best to look in the general direction of an object without the device and then point or place the device in that direction to locate objects. It is easier to scan along horizontal objects such as roads or fences and up and down vertical objects such as trees or walls. Training in the use of all magnifying devices is vital: Magnifying glasses Useful for when you need both hands free for the task e.g. School age children/adults who need to read and write a lot. Up to 20 Dioptres can be prescribed. Always consider if non-optical devices might help instead of or with magnification. For example, a writing stand is useful for relieving posture problems. Do not just give out magnifying glasses, if there is no one to train the person in its use. A person will often reject the device, because they do not know how to see better with it. 1. Uses: ••••• for reading any material ••••• writing ••••• looking at objects from close range 2. Advantages: ••••• range of magnification ••••• both hands free ••••• readily available- e.g. "cataract" glasses can be used as reading glasses •••••

once used efficiently, can be used for long periods

136 3. Disadvantages: ••••• exact reading distance important ••••• Short reading distance with high powered lenses ••••• more fragile than magnifiers (scratching, breaking) ••••• good lighting needed at close distance ••••• often a reading stand is beneficial to bring material close Hand Magnifiers 1.

Uses ••••• reading signs, labels, prices, books ••••• identifying money ••••• inspecting objects such as plants or insects ••••• handwriting 2. Advantages: ••••• easy to carry ••••• available from low to high power ••••• cheap to make or buy ••••• can be used in any position or angle ••••• allows light onto print or objects 3. Disadvantages: ••••• difficult to keep appropriate distance ••••• one hand occupied ••••• difficult to hold steady

137 Stand Magnifiers 1. Uses ••••• Reading from a book or newspaper ••••• Looking at a picture or diagram 2. Advantages ••••• Has a fixed distance for ease of movement ••••• Easy to use ••••• Available from low to high power magnification ••••• Allows light onto print if legs thin and tapered or clear 3. Disadvantages ••••• Keeps one hand occupied ••••• Not useful for activities like writing ••••• Poor posture (bending above lens) ••••• Causes fatigue

138 Telescopes Telescopes can be used for looking at distant objects and activities such as: signs finding and recognising people or animals reading from a blackboard in school finding an entrance to a building watching games. 1. Uses ••••• Reading from a blackboard from a distance >2 m ••••• Looking at objects you cannot get close to, e.g. top of tree, animals 2. Advantages ••••• Makes distant objects appear closer ••••• Can be used in a classroom for blackboard reading or outdoors 3. Disadvantages ••••• Requires very good contrast ••••• Not easy to copy what you have seen, takes time to: (i) Find text on blackboard and read (ii) Write notes down, possibly using other low vision device ••••• Expensive to make ••••• Not easy to use, requires extensive training

139 Electronic Devices Video Magnifiers or CCTVs -A video magnifier, also known as a closed circuit television system (CCTV), allows the user to view an enlarged image of text or pictures that are placed under a camera. The image is displayed on a monitor or television. There are video magnifying systems that are mounted on a permanent stand and are very powerful but not easily moved, as well as portable handheld systems that can travel with the user from location to location, to the store, and back home again. Regardless of which type of video magnifier is used, the concept is the same. The user places the material to be viewed under the camera and the camera projects the image onto the screen. The user can increase the size of the image and change the colour of the text and background. Some models connect to a computer, which allows the individual to use one monitor for both systems. The computer screen can be split, with half the screen showing the information from the computer and half showing the information under the video magnifier's camera. A video magnifier is also considered to be an optical device because

140 it changes the image of the material seen by the eye. Read more about video magnifiers and learn about specific models. Scanners and Optical Character Recognition (OCR) -Scanners have now become a global technology that many people use. When combined with special software that can recognize letters, known as optical character recognition (OCR) software, however, they become an assistive technology tool that can transform print into alternative formats that can be read by people who are blind or visually impaired. For example, one might receive an important document in print. With a scanner connected to a computer the printed document can be scanned and convert into an electronic file that can be displayed as text on the computer monitor. The text can be read using several different methods, such as a screen reading program, a screen magnification program, or a refreshable braille display. A computer word processing program can be used to print the text in the user's choice of print sizes and fonts. Some people with visual impairments use conventional OCR software, while others prefer a specialized scanning system. Some visually impaired users prefer a reading machine, which is a standalone system with a scanner, the OCR software, and voice output.

2.8 Let Us Sum Up Functional academic skills improve the reading writing skills of blind and low vision persons. The techniques are very useful at the time of learning how to read and write. Various reading and writing devices are help for giving success of the goal of these skills. By the use of assessment procedure teachers can be satisfied how much a child can able to learn. Both blind and low vision person can easily learn their academic skills by the use of various types of aids and appliances. These appliances are made on the depends on child's capability. So it must be say that now a days academic procedures are not a barrier for a visual impaired person. 2.9 Check Your Progress 1. What is LMA? 2. Write the importance of reading readiness at the time of braille teaching? 3. How you help a low vision child at the time of reading and writing? 4. Write the difference between aids and devices? 5. List up the name of devices print and braille reading.

3.9 Check Your Progress 3.10 References 3.1 Introduction The teacher of visually impaired children expected to acquire adequate skills for teaching visually impaired children. The skills must be in the areas of expanded core curriculum or plus curricular activities such as sensory efficiency training, orientation and mobility, daily living skills, socio personal skills etc.

Considerable amount of time should be provided to the students in these areas. All these skills are come under independent skills or independent living skills. On the other hand these skills help a blind person for developing their self-confidence and make them mentally strong. By which they can easily overcome their psychological barrier. Or clearly it must be said that independent living skills help the visually impaired person for removing all types of difficulties which they faces day to day life and make them self depended adoptable socialized person. 3.2

Objectives After going through this unit you should be able to: 1.

Describe about independent living skills 2. List out the activities of independent living skills 3. Discuss the techniques of mobility skills 4. Point out the importance of sensory training

145 5. Know the usefulness of daily living skills 6. Understand the needs of social interaction skills 3.3 Independent Living Skills- Meaning, Importance, Components 3.3.1 Meaning

One of the primary purposes of education is to prepare individuals with the tools that allow them equal opportunity to successfully cope with the demands typically encountered in adulthood. In general, these demands involve living with others, managing one's personal life, earning a living, and contributing to and participating within the community. The tools needed to meet these demands include knowledge and skills acquired through academic instruction, social competency developed through interactions with others, specific vocational preparation based on interests and aptitude, and skills of independent living. Independent living,

as seen by its advocates, is a philosophy, a way of looking at society and disability, and a worldwide movement of people with disabilities working for equal opportunities, self-determination, and self-respect. In the context of eldercare, independent living is seen as a step in the continuum of care, with assisted living being the next step. In most countries, proponents of the Independent Living Movement claim preconceived notions and a predominantly medical view of disability contribute to negative attitudes towards people with disabilities, portraying them as sick, defective and deviant persons, as objects of professional intervention, as a burden for themselves and their families, dependent on other people's charity. These images, in the Independent Living analysis, have consequences for disabled people's opportunities for raising families of their own, getting education and work, which, in turn, result in persons with disabilities making up a large portion of the poor in any country. According to philosophical thoughts - "Independent Living does not mean that we want to do everything by ourselves, do not need anybody or like to live in isolation. Independent Living means that we demand the same choices and control in our everyday lives that our non-disabled brothers and sisters, neighbours and friends take for granted. We want to grow up in our families, go to the neighbourhood school, use the same bus as our neighbours, and work in jobs that are in line with our education and interests, and raise families of our own. We are profoundly ordinary people sharing the same need to feel included, recognized and loved." So it may be said that Independent living includes the skills and knowledge an individual needs to direct his or her life at home and in the community.

146 3.3.2 Importance

Skills of independent living necessary for managing adult life include skills related to personal hygiene, eating, dressing, clothing selection and care, food preparation, money management, time management, use of the telephone, cleaning, home maintenance, and community functioning. Within each of these broad areas are additional sub-skills that must be mastered in order to function as interdependent individuals within society. Acquisition of these skills and sub-skills occurs gradually for most children beginning in infancy, primarily through watching adults and older members of society accomplish tasks in which they are used. Children whose interest has been piqued through vision watch carefully, ask questions, practice observed skills in their play, and are physically and verbally guided in their attempts to reproduce the task by competent, older members of society. Spontaneous instruction is provided as needed within the naturally occurring context of the task and often involves demonstration and modelling by competent others, specific feedback on the child's attempt, and encouragement to practice the task, first while helping, then independently. Because acquisition of these skills occurs primarily within home and community environments, academic programs typically do not formally address them. That school programs do not incorporate instruction in independent living

skills, however, does not make them any less critical for post-school success. As is true for other children and youth, the acquisition of independent living skills is crucial for the post-school success of students who are blind or who have low vision. Visual

impairment may impede

the process of the development of independent living skills in several ways,

among which are: •••••

Children may not clearly observe others performing tasks, so may not be aware that the tasks even exist or that other children attempt them in play and real situations. ••••• Children may not clearly observe the whole task or the techniques that others use to perform independent living skills so

may

not have a cognitive model upon which to build skills that includes an understanding of the whole task or its component parts. ••••• Instruction in independent living skills is complicated when learners cannot easily benefit from demonstration and modeling and when the person providing the instruction does not have a well-established understanding of appropriate strategies for addressing the impact of visual impairment on learning. ••••• Children with visual impairment may not

be

given enough opportunities to practice new skills until they become fluent.

147

For students with visual impairments to achieve success in adulthood, they must have well-developed independent living skills prior to transitioning from school to work. Teachers of students with visual impairments (TVIs) must annually assess all students' skills

in each independent living skill area and compare these skill levels to those being acquired by their same age peers, considering that peers often learn about skills long before they use them. Little research has been conducted on the acquisition of independent living skills by students with visual impairments, but there is evidence that these students are delayed in their development of skills in this area. In 2002, Lewis and Iselin compared the interview responses of 10 parents of children with visual impairments ages 6-9 to the responses of 10 parents of same-age students with unimpaired vision to determine the students' level of independent functioning. The 101 survey items focused on hygiene, dressing, clothing care, kitchen, home care, and money, telephone, and community skills. The difference between the level of assistance provided to these students was statistically significant, with children with unimpaired vision clearly demonstrating levels of independence far above their peers with visual impairments. The students with visual impairments were performing only 44% of the tasks independently, while their sighted peers were reported to perform 84% of the skills independently. In fact, students who were blind or who had low vision were not performing 41% of the tasks, even with assistance, while their peers were unable to perform only 14.5% of the tasks independently. In a more recent study of adaptive behaviour in the areas of communication, daily living, and socialization skills of 46 Greek students with visual impairments ages 5 to 18 years old, Papadopoulou, Mestizo, and Agilities (2011) found that the lowest adaptive level of their participants was in the independent living domain. Using the national norms of Vineland Adaptive Behaviour Scales (1984), students with visual impairments scored between the low to moderately low categories (1.46 on a 3 point scale), although when compared to the supplementary normative group, participants were determined to be functioning between the average and above average range. The authors also noted that, while students' abilities in the living skills domain improve with age, the rate of their delay increases. They recommended that instruction in daily living skills be emphasized in school programs to reduce performance gaps. For students with gaps in the development of independent living skills, TVIs must advocate for the inclusion of appropriate goals related to these functional skills on Family Service Plans and Individualized Education Programs (IEPs), as well as for the time and resources to teach these skills. Strong advocacy is key, since people unfamiliar with the long-term outcomes of many students with visual impairments may mistakenly believe that the acquisition of academic skills is of greater importance to post-school success. Experienced educators of students who are blind or who have low vision, however, recognize that students without well-developed independent living skills struggle to use academic knowledge within adult education, vocational, and community environments. A second role, then, of TVIs is to help administrators, parents, and other members of IEP teams to realize the critical importance of including instruction in independent living skills in the curriculum of students who need it. Finally, TVIs must be prepared to provide carefully designed formal instruction in independent living skills to students from infancy until age 22 and to assist students' parents as they acquire experience in introducing, teaching, and reinforcing these skills within the home and community. Instruction should meet the assessed needs of each student; incorporate appropriate alternative sensory methods; focus on safety, fluency, and efficiency; and facilitate development of students' problem solving, organizational, sensory efficiency, and self-advocacy skills.

As much as possible, instruction should occur within naturally occurring environments and contexts, but the limited availability of either or both of these conditions should not prevent instruction from occurring. As part of their responsibilities, TVIs must maintain longitudinal records of students' acquisition of skills and assure that the development of more complex skills within any area occurs when appropriate. Students with visual impairments deserve the opportunity to acquire and use independent living skills similar to those of their peers. Similarly, teens with visual impairments deserve to leave high school ready to function in the adult school, community, and work environments to which they transition. Through assessment, advocacy, collaboration with families, targeted formal instruction, and a commitment to positive post-school outcomes, these objectives are much more likely to be achieved. It is the position that children and youth with visual impairments require carefully designed instruction in independent living skills that is

facilitated by qualified individuals who understand the impact of visual impairment on the acquisition of general information and learning. Development of independent living skills is vital for full integration in society. Specialized assessment and instruction must be provided. In addition, sufficient time, resources, and support must be available to teachers of students with visual impairments to allow them to address all the educational needs of their students, including those related to independent living skills. Teachers, parents, and administrators must work together in these efforts to achieve the promise of equal opportunity, the overarching goal of education.

149 3.3.3

Components The components of independent living skills are as follows- ✓✓✓✓✓ Home Living ✓✓✓✓✓ Household & Money Management ✓✓✓✓✓ Transportation ✓✓✓✓✓ Law & Politics ✓✓✓✓✓ Community Involvement ✓✓✓✓✓ Personal Safety ✓✓✓✓✓ Recreation & Leisure ✓✓✓✓✓ Interpersonal Relationships ✓✓✓✓✓ Self-Advocacy / Self-Determination

On the basis of these components various activities are included in the expanded core curriculum's syllabus. Which are most commonly named as orientation and mobility skill, daily living skill, personality development skill etc. 3.4

Orientation and Mobility-Need and Importance, Techniques of Teaching Mobility Sighted Guide and Pre Cane, Cane Techniques and Mobility Aids

Orientation and Mobility

Movement is a building block for learning. As a child explores his world and has physical contact with it, learning takes place. Children with visual impairments typically need encouragement to explore their surroundings. To them the world may be a startling and unpredictable place, or it may not be very motivating. Orientation and mobility training (O & M) helps a blind or visually impaired child know where he is in space and where he wants to go (orientation). It also helps him be able to carry out a plan to get there (mobility). Orientation and mobility skills should begin to be developed in infancy starting with basic body awareness and movement, and continuing on into adulthood as the individual learns skills that allow him to navigate his world efficiently, effectively, and safely. Orientation and mobility training actually began after World War II when techniques were developed to help veterans who had been blinded. In the 1960s 150 universities started training programs for Orientation and Mobility Specialists who worked with adults and school aged children. In the 1980s the O & M field recognized the benefit of providing services to pre-school aged children. Today, orientation and mobility specialists have developed strategies and approaches for serving increasingly younger populations so that O & M training may begin in infancy. Orientation and Mobility or O&M is a profession which focuses on instructing individuals who are blind or visually impaired with safe and effective travel through their environment. Individual O&M Specialists can work for schools, government agencies or do private contracting for their services. The Academy for Certification of Vision Rehabilitation and Education Professionals offers certification for vision rehabilitation professionals, in the USA. History of Orientation and mobility Orientation and mobility training actually began after World War II when techniques were developed to help veterans who had been blinded. In the 1960s universities started training programs for Orientation and Mobility Specialists who worked with adults and school aged children. In the 1980s the O&M field recognized the benefit of providing services to pre-school aged children. Today, orientation and mobility specialists have developed strategies and approaches for serving increasingly younger populations so that O&M training may begin in infancy.

The profession of Orientation and Mobility began to develop during, and immediately after, World War II, when soldiers who had been blinded in battle were sent to recuperate at Valley Forge Army General Hospital before entering Avon Old Farms Convalescent Hospital, the U.S. Army's former experimental rehabilitation centre for blind soldiers in Avon, Connecticut.

Orientation and Mobility Specialists An Orientation and Mobility (O&M) Specialist provides instruction that can help you develop or relearn the skills and concepts you need to travel safely and independently within your home and in the community. O&M Specialists provide services across the life span, teaching infants and children in preschool and school programs, as well as adults in a variety of community based and rehabilitation settings.

Although Orientation & Mobility Specialists are primarily responsible for O&M training, their work may not always be done directly with the child. When the child is very young, for example, the O&M may provide consultation to the vision teacher, occupational therapist, physical therapist, early intervention specialist, and the family.

151 3.4.1 Need and Importance Orientation and mobility (O&M) training helps children and adults who are blind or visually impaired know where they are, where they want to go (orientation) and how to get there safely and independently by walking or using transportation (mobility) The Department for the Blind and Vision Impaired offers travel skills assessments and training, orientation technique training, and instruction in how to get around independently, to include: •••• Using hearing, touch and smell to gather information about the world •••• Learning spatial concepts to understand the relationships that exist between objects in the environment •••• Using the cane to clear a safe path and locate objects along the way in both indoor and outdoor environments •••• Asking for or declining assistance •••• Independently finding your destination •••• Techniques for crossing streets, such as analysing the shape of an intersection? determining if traffic is controlled by a stop sign, yield sign, a traffic light, or no control ••••

Problemsolving skills

to determine what to do if you are disoriented or lost or need to change your route •••• Using public transportation and transit systems

Specialists provide services to adults in a variety of community based and rehabilitation settings. Orientation and Mobility services are provided in your home, college, community, city and work site. Importance of Orientation and Mobility in Rehabilitating Individuals who are Blind or Visually Impaired Orientation and mobility (O&M) is a vital program for the blind and visual impaired and its importance can never be over emphasized. O&M is important because instruction covers the following areas? "

Sensory development, or maximizing all of your senses to help you know where you are and where you want to go 152 ••••

Concept development, which includes body image, spatial, temporal, positional, directional, and environmental concepts

•••• Motor development, including motor skills needed for balance, posture, and gait, as well as the use of adaptive devices and techniques to assist those with multiple disabilities •••• Sensory development, which includes visual, auditory, vestibular, kinaesthetic, tactile, olfactory, and proprioceptive senses, and the interrelationships of these systems

•••• Residual vision stimulation and training •••• Upper and lower protective techniques •••• Locating dropped objects

•••• Trailing •••• Squaring-off ••••

Using a cane and other devices to walk safely and efficiently •••• Soliciting and/or declining assistance ••••

Following directions •••• Utilizing landmarks •••• Search patterns •••• Compass directions •••• Route planning ••••

Locating destinations using various techniques and tools •••• Analysis and identification of intersections and traffic patterns •••• The use of traffic control devices •••• Techniques for crossing streets •••• Techniques for travel in indoor environments, outdoor residential, small and large business districts, mall travel, and rural areas ••••

Techniques for crossing streets, such as analysing and identifying intersections and traffic patterns Problemsolving skills to determine what to do if you are disoriented or lost or need to change your route

153 •••• Using public transportation and transit systems ••••

Evaluation with sun filters for the reduction of glare •••• Instructional use of low vision devices 3.4.2 Techniques of

Teaching Mobility When planning an O & M program for children the focus of training may include such things as: ••••

Sensory awareness: gaining information about the world through hearing, smell, touch and proprioception.

When a child cannot access his world efficiently through his vision, he must learn to use his other senses more effectively.

Systematic instruction is needed to develop the other senses for use in travel and finding things in the environment.

He must understand that some of the sounds and smells and textures he experiences can be used as permanent markers (landmarks) to let him know where he is in the world. Other pieces of information may be there sometimes and not at other times (clues) such as the sound of the water fountain. Developing sensory awareness is critical for the child with visual impairments or blindness.

Sounds, when not paired with clear visual information, can be very confusing. Try sitting in a busy mall or park for a period of time with your eyes closed. You will probably hear sounds you can't identify and be tempted to open your eyes, to try to pair a sound to its source. You might assume that sounds which get louder and louder are coming towards you because of your visual knowledge of the world. A child with a visual impairment may not make the same assumption. The ringing noise he hears may not mean "telephone" or that the honking sound may not mean "car." He needs help in learning to use his hearing to interpret the world around him. If his hearing is impaired even to a small degree that task will become much more difficult. Close your eyes and plug your ears while you stand on a busy street corner. Can you tell which way the traffic is flowing or when it will be safe to cross the street? Are you startled or distracted by other noises you hear? Children need to learn to localize sounds and use sound clues for orientation, straight line travel, and safety. Though we may not be aware of it, we know much of the world through touch. However, if the things you touch or that touch you feel funny, or hurt, you may become resistant to using touch to examine things in your environment. Touch alone may not be helpful in identifying an object if you can't touch the whole object at one time. Is 154 the furry thing a cat or a rabbit? If you aren't touching the ears or the teeth or the tail you might not know. Developing the tactual sense will help the child in ways that range from finding a toy he dropped on the floor to feeling the difference between the curb and the street with his cane. Normally I don't pay much attention to smells unless they are extremely pleasant or offensive, but I might use that kind of information to help me know exactly where I am in certain environments. Smells can also serve as landmarks and clues for environmental awareness. For example, the smells that can be found in my kitchen differ greatly from the smells in my bedroom. I can also smell food being cooked near mealtime in my kitchen, but after a meal I am more likely to smell the soap used in the dishwasher. If I am looking for a clue to my location, I need to know that both of those smells might mean I'm in the kitchen. The gym at school, unlike my kitchen at home, might always smell about the same. If I have no sight, this smell, especially combined with other clues and landmarks, might help me know that I am in the gym. It is important for children with visual impairments to participate in activities that enable them to fully use their other senses. Learning to interpret the information they tune in to is equally important. Parents and educational staff, with support from the O & M, can do a lot to help children develop their other senses. •••••

Spatial concepts: realizing that objects exist even if not heard or felt, and understanding the relationships which exist between objects in the environment. "Go down the street three blocks and turn right at the corner. I live in the upstairs apartment of the large, red brick building on the left." Pretty clear directions right? What if you don't know "blocks" and "corner" or "upstairs" and "left"? Doesn't "down" mean under? How large is "large?" When vision is impaired these concepts are much more difficult to understand and need to be taught. How do you teach the concept of "corner" without vision? Do you touch corners or draw corners? If you can touch a corner or draw a corner, where do I find the corner to touch when I am walking along the street? Orientation and mobility specialists work to develop distance, size and directional concepts in children with visual impairments. Mom and Dad, and Mrs Henry the art teacher, may work on these concepts too, but having the support of an O & M would likely make their job much easier. Our joints and muscles give us feedback about where our body parts are positioned. This is our proprioceptive sense. Proprioceptors located in the muscles and joints tell us if we are slumping or standing up straight, if our fingers are curled or extended, etc. Our vision system and our proprioceptive system work closely

155 together. When vision is impacted, so is our proprioceptive sense. Children with visual impairments generally need help to learn where their bodies are in space, and in relation to things in the environment. The physical therapist and occupational therapist, along with the O & M, can work directly with the child. They may also be able to suggest specific activities for the family, to help their visually impaired child develop the proprioceptive sense. •••• Searching skills: locating items or places efficiently. By using this skill find out object in unfamiliar surroundings and also save time. •••• Independent movement: this includes crawling, rolling, walking, etc. Most children with visual impairments are capable of learning routes in familiar environments. They learn to use landmarks and clues to help them know where they are along a particular route. They learn specific adaptations to aid them in their movement. These might include understanding that tactual markers on doorways identify the gym or the restroom, using an adaptive mobility device or a cane to identify obstacles and drop offs, or locating a street sign using a monocular. A primary goal of orientation and mobility training is to help each child with visual impairments achieve independent movement to as great a degree as possible. Some children may be preparing to get a dog guide, or learning how to access public transportation to get across town to a job. For children with additional disabilities, independent movement might focus on traveling independently in a wheelchair, or learning how to help get you into a van using a lift. It might mean helping the child learn to control the speed of movement on his walker as he goes down a ramp. Independent movement is tied to growth in other areas, such as communication and socialization. For example, though a child may not be able to tell you he's hungry, if he can take you to the kitchen you will probably understand that he wants something to eat or drink. Peers are more likely to invite your daughter to go to the mall if she can keep up with the group by using sighted guide technique or traveling with a cane. Going where we want when we want gives us control and allows us to make choices. •••• Sighted Guide: using another person to aid in travel. While principal objective of orientation and mobility training is attaining freedom in movement, help of another person is essential under certain circumstances. A visually impaired may require assistance of sighted guide while crossing busy road, moving in a less familiar environment, searching a visual sign or moving in a crowded place.

156 ••••

Protective techniques: specific skills which provide added protection in unfamiliar areas. Can be used for protection from such vertically placed obstacles or low obstructions. And also used in alone walking. ••••

Cane skills: use of various cane techniques to clear one's path or to locate objects along the way.

It has been and remains the primary tool utilized by the visually impaired individual in his travel through the environment. The purposes of the cane are- protection, feedback and identification. Although Orientation & Mobility Specialists are primarily responsible for O & M training, their work may not always be done directly with the child. When the child is very young, for example, the O&M may provide consultation to the vision teacher, occupational therapist, physical therapist, early intervention specialist, and the family. It is important that an O & M Specialist be a part of the team because it is the O & M who must build upon these early concepts to meet long range goals. Even visually impaired children who have motor impairments need training in orientation and mobility. Though their O & M goal may not be independent travel, they may need O&M to participate more fully in events in their environment. For example, understanding that child's wheelchair is in front of him, can help him find it to assist with the transfer to the chair. Knowing that his switch is on the right side of his lap tray may allow him to play his CD player whenever he choose, instead of having to wait for someone to come help him. Even if he is not yet walking, it would probably be good to know that he could listen for the sounds mom is making in the kitchen to help him find the way to her. Children who are deaf-blind also need orientation and mobility training. Because their other distance sense (hearing) is affected, orienting to their environment and traveling safely becomes even more important. Orientation and mobility specialists have specific knowledge which is critical to the child with deaf-blindness. Orientation and mobility is important for every visually impaired child. It does not matter how young or old he is, how physically active or inactive, how much vision he has, or how smart a child he is, there are probably skills that he needs to develop or refine in the area of orientation and mobility.

3.4.3 Sighted Guide Technique

Sighted guide is a technique originally developed for people who are blind. It is also useful for those with low vision who are unsure of their bearings in an unfamiliar environment. Remember, always ask if any help is needed; not everyone needs or wants sighted guide assistance.

157 •••• Basic Sighted Guide Position and Alignment: The basis of the sighted guide technique is the blind or low vision person holds the guide's arm lightly above the elbow and allows the guide to walk one-half step ahead. This allows him or her to feel and follow the guide's direction. To begin sighted guide, the guider should touch the arm of the person being guided with the elbow preferable to use. He or she can then take the arm above the elbow. If someone needs extra support for walking, the guider should bend the supporting arm, parallel to the ground so he or she can apply weight to the arm. Guiding signals are helpful when a change in motion is needed, for example, a brief pause at the edge of a curb. Verbal clues are also helpful; "We are approaching a curb, the curb is slanted upward." So some important rules are as follows-

1. The sighted guide gives verbal cue ("take my arm/wrist") and/or nonverbal cue (touching the back of the person who is blind's hand with the back of the guide's hand).
2. The person who is blind should stand next to and slightly behind sighted guide, facing in the same direction as the guide. Therefore, the person who is blind is always at least a half step behind the guide.
3. The person who is blind's upper arm remains close to his or her body, with forearm and upper arm making a right angle at the elbow, with the forearm, wrist and fingertips aiming directly forward. The wrist is neither flexed nor hyper-extended, and the forearm neither angles toward the midline of the body nor away from the body, but aims straight ahead. The person who is blind grasps the guide's arm or wrist with the fingers toward the inside and the thumb toward the outside of the guide's arm.

158 4. The guide's arm is grasped at a location such that the person who is blind's upper arm and forearm form a right angle. The height difference determines this. A pre-schooler may grip an adult's wrist, whereas a tall person who is blind may need to grip a short guide's arm just under the armpit. The right angle allows for movement up or down for steps or curbs, etc.

5. The person who is blind's shoulder is directly behind guide's opposite shoulder, so that the pair are approximately one and one-half persons wide, except when traversing narrow passageways in which only one person can safely pass at a time.
6. The person who is blind should be responsible for maintaining orientations as well as the proper grip and alignment with the guide, but if he or she is incapable of doing so, the sighted guide is responsible for monitoring this. The person who is blind's non-grip hand can be used to confirm proper alignment by touching the guide's shoulders and aligning him/herself accordingly. The person who is blind can also assist with doors when appropriate, and the guide is responsible for the decision to transfer sides as needed to traverse doorways based upon the capabilities of the person who is blind.
7. The sighted guide is responsible for the safety of the person who is blind at all times, regardless of the errors on the person who is blind's part. The guide must be especially careful to monitor obstacles at various levels from head to toe. These obstacles not only include furniture, fixtures and people, but also overhanging head-high obstacles as well as slight irregularities in the walking surface, such as carpets, doorway mouldings and changes of texture in the walking surface. If the person who is blind trips, it is the guide's responsibility to support the person who is blind. The guide should choose or adjust walking pace to accommodate the needs of the person who is blind.

•••• Narrow door or passage: When going through a narrow door or passage, move your guiding arm backward toward the small of your back,

so the person being guided can step in single file behind you

1. The guide gives a nonverbal cue for the person who is blind to get directly behind the guide by moving the guiding arm back, placing the wrist in the small of the guide's back.
- 159 2. The person who is blind slides his/her hand down to the guide's wrist, stepping diagonally backward to walk directly behind the guide. The person who is blind extends his or her arm in order to avoid stepping on the guide's heels, walking one full step directly behind the guide. The non-grip hand can be used to confirm proper single-file alignment.
3. When the person who is blind is much taller or has a much longer stride than the guide, the guide may wish to extend his/her guiding arm backward from the small of the back. Although uncomfortable, it allows more room for the person who is blind's greater stride.
4. The guide may choose to reduce the pace and shorten stride slightly while going through the narrow space, then resume arm position, pace and stride after passing through the narrow space.

•••• Reversing Directions or Transferring Sides: (Note: either party can initiate a change of direction or a change of sides, after notifying the other of the need to do so.)

1. Reversing directions: The pair comes to a complete stop, the person who is blind releases grip, and the pair turn toward each other while executing a 180 degree

160 turn. The guide then re-establishes contact and the pair resume proper position and grip, traveling in the opposite direction. 2. Transferring sides: There are two methods of transferring sides; based upon the ability and preference of the person who is blind. o The most stable method is the grip method, done after the pair comes to a dead stop. The person who is blind places the back of his/her free hand just above his/her grip on the guide's arm and moves the original grip hand across the guide's back to the guide's other arm as he/she sidesteps into the new position on the guide's other side, resuming grip with the appropriate hand. o The slide method of transfer can be done while stopped or while traveling, depending upon the abilities of the pair. The back of the person who is blind's free hand contacts the guide's arm just above the original grip hand, with the fingertips pointing toward the guide's opposite arm. The person who is blind then releases the original grip and turns 90 degrees toward the guide's opposite arm, trailing across the guide's back until the guide's opposite arm is gripped and the new alignment is achieved. Since trailing is less secure than a firm grip, and since this method required a change of direction, it is not recommended for lower functioning or physically unstable individuals. •••••

Curb: When approaching a curb, pause briefly at the very edge of the curb and say whether the curb goes up or down.

161 •••••

Stairs: When

approaching stairs, come to a stop at the edge of the first step and say whether the stairs go up or down and where the railing is located. The person being guided

will follow one step behind, holding your arm with one hand and the handrail with the other. Pause after completing the stairs. 1.

In an unfamiliar area, the guide should indicate the presence of a level change, particularly novel types of stairs (deep, narrow, curved, etc.). 2. With both ascending and descending curbs and stairs, the guide must take care to approach the stairs perpendicularly. In this way, the person who is blind is aligned so as to take the next step either up or down as the guide's movements indicate. 3. The guide brings the person who is blind alongside to the edge of the steps so that

neither person's toes extend over the edge of a descending step or under the extended edge of an ascending step. 4. When a railing is available, it is best to have the person who is blind take the railing before the guide takes the first step, unless he/she requests otherwise. 5. The guide takes the first step up or down in front of the person who is blind. The person who is blind waits until the guide has taken the first step, and both people work together to stay in step, with the person who is blind one step behind the guide at all times. 6. The guide is responsible for monitoring and making

adjustments so that when the guide is at the top or bottom, he or she pauses to indicate this while the person who is blind takes the last step. The guide's arm then moves directly forward (rather than up or down and forward) to indicate the level surface. •••••

Chair: When approaching a chair, place the hand of the person being guided on the back or side of the chair if possible, so he or she knows where the chair is and which way it is facing. He or she can then decide where to sit 1. Place the person who is blind's hand on the back of the chair and/or guide the person to the chair so that his or her knees or shins gently contact the edge of the seat. Tell the person that they are facing the front, back or side of the chair. For table/chair combinations or with stools or other unusual seating, explain the situation first, and then place the person's hand on it.

162 2. In an auditorium or with similar narrow seating, the guide first explains the situation, and then enters the aisle by side-stepping side-by-side with the person who is blind, maintaining contact with the person who is blind by touching the backs of each other's hands until they have located their respective seats. Allow the person who is blind to seat him/herself. •••••

Door: When coming to a door, stop first, then say whether the door opens toward or away from you, and whether it opens to the right or the left. The person being guided can then move to the appropriate side. Open the door and proceed. 1. The guide gives the narrow passageway signal, always going through the door first. The guide's movements to open the door can sometimes be interpreted by the person who is blind as to whether the door is a push or pull door, as well as to which side the door opens. When approaching a pull door, the guide must stop farther back than he/she normally would, reach forward and pull the door back without stepping backward into the person he/she is guiding. 2. With both push and pull doors opening to the person who is blind's side, the person who is blind should anticipate contacting the door by putting his or her arm into a modified hand and forearm position. If the person who is blind does not do so, the guide must be responsible for assisting as

163 necessary, while maintaining proper alignment through the doorway so that the person who is blind maintains the proper alignment through the doorway. 3. The person who is blind is responsible for holding the door, which opens to his or her side. The sighted guide is responsible for seeing that the person who is blind is on the side away from the door opening if the person who is blind cannot hold the door. The guide is also responsible for holding the door or monitoring in such a way as to avoid injury to either party. The person who is blind's hand should never slide on the door while it is opening or closing, nor should the door be contacted on the edge, but as close to the middle as possible. •••••

Escalators and revolving doors : When approaching escalators and revolving doors, use techniques similar to those for stairs, curbs, and doors. If the person you are guiding is uncomfortable, use stairs or regular doors. Buildings with escalators or revolving doors are required to have stairs and regular doors. ••••• Car : When helping a visually impaired person into a car, place one of their hands on the door handle and have them locate the edge of the car roof with their other hand. Thus allowing the guided person to seat themselves.

164 ••••• Other Important Tips to Remember : 1. be considerate of the person who is blind's need to know where he/she is, who and where you are, and who else is present. Encourage others to introduce themselves so that the person who is blind can locate them and connect names with voices. 2. Never leave that person unless you first inform them. Make certain that he/she knows where you are going and when you will return, etc. If he or she is not sitting, it is helpful for them to have something substantial to touch (chair, table or wall) in order to maintain his or her orientation. ••••• Final thoughts: These techniques are useful in numerous circumstances. Family and friends often use them in daily activities such as shopping, dining out, and much more. Co-workers of those with low vision may find these techniques useful when assisting their colleagues. Healthcare professionals and other caregivers also find these techniques beneficial. If you or someone you know will benefit from additional information on the sighted guide technique please contact the SightConnection office.

165 3.4.4 Pre Cane Technique The Trailing Technique Trailing is a technique of using the back of the hand with fingers curled slightly inward and arm slightly extended to trail a wall or around an object such as a table. The Trailing Technique can help to locate a door, walk in a straight line, or detect the position of objects in front of the person on the same side of his body as his extended arm. This technique can provide him with useful information about everyday objects, obstacles, and potential hazards that he may encounter as the time of move about own home. It can also provide him with a feeling of security while the walk, by allowing him to remain in contact with walls, countertops, desks, tables, or other types of stationary surfaces. It's important to remember that this technique will not warn you about approaching drop-offs, such as steps and stairs. For maximum protection, he should use the trailing technique in combination with either the upper or lower body protective technique, depending upon his needs in a particular environment. It is essential to impart training to visually impaired persons as it: 1. Begin along a straight stretch of wall in an uncluttered area. Stand with the side of own body about 6 inches from the wall. 2. Extend his hand in front of him at approximately hip level and angled downward toward the floor, about 12 inches from own body. 3. The back of his hand should be in contact with the wall, with his fingers slightly cupped toward his palm. 4. This will prevent him from injuring his fingers if they make contact with an object. His fingers will also act as "bumpers" to warn him about objects that he may encounter. 5. Walk forward slowly while holding his arm in this position, keeping the backs of his fingers, especially the knuckles of his ring and "pinks" fingers, in contact with the wall. 6. Make sure that the back of his hand is always in contact with a surface while he is moving. 7. When he make contact with or locate an object, take a few moments to examine and identify it. 8. If he comes to a doorway, walk across the opening and resume trailing on the other side.

166 9. For maximum protection when crossing the door opening, it is recommended that he use either the Upper Body Protective Technique or Lower Body Protective Technique, depending upon the particular environment. 10. Initially, he may be able to hold this position for only a minute or two, but with repeated practice he will be able to maintain this position for longer periods of time. Search pattern It can be frustrating when a person can't locate something he has dropped. Some useful rules can help him locate dropped objects more easily. As search, remember to protect own's upper body, particularly his face and head. Also be sure to check with the doctor if he have a medical or eye condition that prevents from bending over, squatting, or kneeling. These search techniques can be used whether dropped something on the floor or a work surface such as a desk, table, or counter. 1. First stop whatsoever the person is doing. 2. Listen for the sounds the object makes when it falls to help you determine its general location. If the object falls on a soft surface, such as carpeting, it may not make a loud noise, but it is likely to remain close to the point where it fell. Objects that fall on harder surfaces, such as tile or wood, will make a louder sound but are also more likely to bounce or roll away from the point of impact. 3. Face in that direction. 4. If can determine the general location of the object, plant the foot with the toe pointing in that direction. 5. When searching for a dropped object, follow a system. Begin searching close to own body and then move outward. Search with own hands (not only with your fingertips) in overlapping semicircles, for example, or overlapping rows from side to side. Don't forget to check between and around own feet. 6. Try to search with one hand at a time, using the other to protect and stabilize ownbody. 7. Being a systematic search in the following pattern: i) Circular: move hand in ever increasing circles
ii)

Perpendicular: follow a square pattern making a series of horizontal movements each separated by one hand's width
167 8.

Instead of using own hands, stand in one place and search with own feet, or use a yardstick, broom handle, closed umbrella, or cane to search the area systematically. 9. Use a broom to sweep the area and check the pile that he has collected. He can also use a broom if he has balance problems, have difficulty bending over, or areafraid of falling. 10. The person can also sit in a chair and use own hands or feet to search. 11. Always remember to protect head and face as the time of searching. 12. Use own visual memory in combination with these search techniques to receive maximum feedback from the surroundings. Protective techniques Protective techniques are designed to be used to protect one when traveling indoors or outdoors. There are several different ways can protect them when they are traveling. There are two techniques called the upper and lower protective techniques. The upper protective technique is to protect individuals from overhanging dangers that a cane may not detect. Either arm is extended in front of the face or upper chest area. The elbow is bent and the palm is facing away from the face. The arm should extend approximately six to twelve inches away from the face. The traveller then can detect doors, walls, cabinets, outdoor overhanging trees or branches, etc... The lower protective technique is to detect things waist down. The arm is extended diagonally across one's midline. The palm should face towards the body and be approximately six to twelve inches away from the individual. The traveller can use this technique to detect chairs, tables, desks, beds, etc... The techniques can be used individually or together. They can also be used in conjunction with a cane in the opposite hand. Protective techniques are meant to be used temporarily to detect immediate danger in one's pathway. Once the object is found, the arm can be lowered. A final tool that can be used is trailing. Trailing can be use while walking along a wall, fence, building line, or any straight pathway. The object of trailing is to keep a straight line of travel and to help find objects along the pathway. When trailing, one's arm is extended along the wall, approximately one foot, in front of them. The fingertips should be curled to protect from door jams and other hazards along the way. One should then slide their arm along the wall. Again, this technique can be used alone or in conjunction with a cane or other protective techniques. Hopefully, these safety techniques will come in handy on their next trip near or far.

168 Support 3.4.5

Cane Techniques Mostly and widely used, very practical and economical way of mobility is cane technique. The use of the cane is systematized by Dr. Richard Hoover so it is known as Dr. Hoover's cane and it is painted white so it is also known as 'white cane'. Many visually disabled feel shy to use the cane

is the symbol of INDEPENDENCE. It is the extension of the sense of touch. The cane has three parts; they are grip, stuff and tip.

The grip is generally of rubber for firmness. The stuff is a long hollow aluminium tube. The tip is generally of nylon.

There are three types of canes available long cane, folding cane and electronic cane. All the canes have almost the same parts.

The cane techniques are simple, universal and can be applied even in a relatively unknown environment. The length of the cane is determined by the height of the user, generally 90 centimetres, should reach the breastbone when held vertically and should touch the ground about one meter in front when a person holds it. Holding the Cane: Ø Person can hold the cane in either hand. Ø Grip: while holding the cane thumb should be on the front of the top, forefinger should be fully extended and second finger is curled behind to support the cane. But other fingers should be kept relaxed and elbow should be slightly bent near the body. Ø Hand position: the hand holding the cane should always be in line with the middle of the body and in front of the navel.

169 Using the cane: Ø Wrist movement: the cane is moved from side to side by the flexion and extension of the wrist with the tip touching the ground lightly at each movement. The arm should not be moved. Ø Arc: the cane tip should touch the ground a little wider than the width of the person's body. Ø Instep: simultaneously with the extension of one foot forward, the cane should move in the reverse. For example, as the left foot steps forward, the cane moves to the right and as the right foot comes forward, the cane goes to the left. Ø Rhythm: the cane tip is lifted just clear of the ground as it traverses between two points of contact. The cane should move back and forth at steady speeds as the visually impaired person walks. Ø Shorelining: the technique of following a fence, wall or side of a pavement with a cane is called Shorelining. The person should swing the cane to touch the wall, swing it back to the other side and as the person walks the cane should hit the wall lightly on one side of the arc and ground on the other.

170 Ø Ascending and descending: When going down stairs, let the cane tip fall onto the next step and don't swing it in case other people are trying to go down the stairs too. When going up the stairs, the cane will hit the first step when you are on the ground level. Grab the cane so it's relatively vertical, and let the cane hit each step as you ascend. Once you reach the top, go back to swinging. When going down the stairs, let the cane tip fall onto the next step and then step down to it. For a smoother descent push the cane forward along the step and allow the cane drop two steps below, so that it is always a step ahead of you. Keep the cane from swinging to allow other people to use the stairs. When pushing the cane forward doesn't result in it dropping you know you've reached the end of that set of stairs. To avoid a nasty fall, remember that after the cane has reached the bottom of the stairs, you still have another step to take. 3.4.6

Mobility Aids Canes: The following

types of canes are available: i.

Symbol Canes: Made of sections of light metaltubing, generally aluminium or its alloys, joined throughthe centre by means of an elastic cord. The canes foldup conveniently for carrying in the pocket or handbag. When required for use, the top section is held andothers automatically fall into position.

Devised for portability and not intended to be usedother than as a guide aid and an indication that theuser is a visually impaired person. This cane is popularlyknown as a Braille folding stick. ii. Guide Canes: A stronger version of the symbolcane and intended to be more of a mobility aid butnot a means of support. The four sections, coveredwith ribbed

171 plastic

sleeving, are joined through the centre by means of an elastic cord enclosed in nylonsleeving. It is fitted with an elastic loop handle anda standard nylon tip.

iii.

Long Canes: A wooden or aluminium stick of 85to 90 centimetres. Three models are available:

rigid,two piece, and four piece. The aluminium cane is generally sleeved with PVCmaterial, having a rubber grip and a nylon tip withor without a crook.

iv. Electronic Travel Devices:

An ETA is describedas a device that sends

out signals to sense the within a certain range or distance, processes theinformation received and furnishes the person withrelevant information about the environment. Most ofthese devices are based on integrated circuits and emitsound or tactile signals.

As ETAs are not available and prevalent in India, itis not very necessary to give description of these devices.However, for the sake of information, these devices are listed below: •••• Lind Say Russell E-model Path Sounder •••• C 5 Laser Cane

•••• Ultrasonic Torch •••• Sonic Guide •••• Light Probes •••• Mowat Sonar Sensor •••• Nottingham Obstacle Sensor

•••• Electro-cortical Prosthesis •••• Electro Roftalm •••• AFB's Computerized Travel Aid •••• Polaroid Ultrasonic Travel

Aid

Mobility Show Card: A plastic show card to help visually impaired persons to cross busy roads and to hail a taxi. Mini Beeper: A battery operated, hand-held electronic gadget having application

Electronic Aids for Orientation and Mobility

There are a variety of O&M devices that individuals with visual impairment use. Most are considered "low tech" because they are very simple devices, typically a cane or adaptive

172 mobility device. These are the devices that most people with visual impairment will use for two good reasons: (1) they are relatively inexpensive to purchase and maintain, and (2) you typically must be able to use these basic devices (especially a cane) before you can learn to use other types of mobility devices or strategies such as ultrasonic technology or dog guides. Your O&M specialist can show you canes and adaptive mobility devices and will be able to dispense these "low tech" devices to your child. There are also other O&M devices, more "high tech" and less well known, which we thought you might like to learn about. These devices can only be issued by an O & M Specialist with ETA certification. The ETA certified O & M Specialist must also provide training in the use of these devices. Non-ETA certified O & M Specialists may not dispense or train individuals using these devices.

The Sonic Pathfinder is a head mounted ultrasonic mobility device designed for outdoor use in conjunction with a long cane, dog guide or residual vision. The Sonic Pathfinder gives the user advance warning of objects which lie within the travel path. The distance and position of a detected object is signalled via the ear pieces using the eight tones of the musical scale. The Sensory 6 detects objects that are farther away than a long cane, and the user hears tones that indicate the distance to the objects. As objects are approached, the tones become higher pitched. The Sensory 6 is not intended to be the only travel aid. It should probably be used in conjunction with another aid, such as a cane. The MOWAT Sensor is a small handheld device that uses high frequency sound to detect objects within a narrow beam. The entire sensor vibrates if an object is present. To avoid confusion, the sensor responds only to the closest object within the beam and the vibration rate increases as the user approaches the object. The Polaron is a compact aid that utilizes ultrasonic technology to detect objects within four, eight, or sixteen feet. The Polaron may be used as a secondary aid to a standard long cane, or with a guide dog. When an obstacle is within range, the Polaron either vibrates or emits a sound. The Polaron is designed specifically for the blind, visually impaired and deaf-blind wheelchair user. The Wheelchair Pathfinder is a set of small rectangular boxes mounted to the front of the wheelchair. Lasers point downward while ultrasonic beams are transmitted in front and to the sides of the wheelchair. When the beam contacts an object, it bounces back to 173 a receiver, triggering an audible warning signal or optional tactile signal. The Wheelchair Pathfinder has forward detection (an intermittent beeping sound), side detection (a continuous tone on the side where the object is) and step detection (a low pitch signal within 4 feet in front of a drop off). The Laser Cane operates with three lasers that emit invisible beams of light from the cane. The beams detect drop offs and obstacles at different heights and distances. In this way, the cane provides the user with advance warning of obstacles in his/her path through an audible and tactile alarm system. There are three distinctly different audible tones: high, middle, and low pitched. The vibrating unit, known as the tactile stimulator, signals the index finger when there is an obstruction straight ahead. The Mini Guide is an ultrasonic device that detects obstacles from 1.5 to 26 feet away to augmentative information from other mobility aids such as cane or dog guide. This hand held electronic travel device uses ultrasound to detect objects and gives tactile or auditory feedback by vibrating or chirping more rapidly as the user approaches an object. The device can help a blind person avoid obstacles and overhangs, locate landmarks or items such as mailboxes or trash cans and find open paths through crowds. The Wicab Brain Port device takes information gathered from a small digital camera in a pair of glasses and sends it to a 'lollipop' electrode array that sits on the user's tongue. The camera then transmits the light information to a small base unit about the size of a cell phone. The base unit then converts the light information into electronic impulses. The Handheld Mobility Device is a small device which the user points around the surrounding. Once the handheld device detects a particular object the device will vibrate. The vibration enables the user to identify that there is an object nearby. A fainter vibration for a relatively far object and a stronger vibration to a near one. These devices should be used with a cane. The C2 Compass is a miniature handheld battery operated 8 point compass with digitized voice output. The compass is contained in a semi-transparent light blue enclosure. At the top there is the speaker and the activation button. A 3 position slide switch on the side is used to switch the compass off and select one of the two inbuilt language or voices. The GPS although used in identifying one's location. GPS (GLOBAL POSITIONING SYSTEM) devices also help blind persons in travelling independently. It determines and verifies correct travel route.

174 3.5

Daily Living Skills- Assessment of Needs and Techniques of Teaching Age Appropriate Daily Living Skills 3.5.1

Assessment of Needs of Daily Living Skills Activities of daily living (ADLs) are basic self-care tasks, akin to the kinds of skills that people usually learn in early childhood or a person employs daily to maintain and keep himself on par with the others and certain activities that are must for a person to live and dose on a day to day basis are called activities of daily living which also known as 'survival skills'. They include feeding, toileting, selecting proper attire, grooming, maintaining continence, putting on clothes, Bathing, walking and transferring (such as moving from bed to wheelchair). ADLs are often mentioned by geriatric care professionals in connection with instrumental activities of daily living, which are slightly more complex skills. ADLs are occasionally referred to as basic activities of daily living (BADLs). Instrumental activities of daily living (IADLs) are the complex skills needed to successfully live independently. These skills are usually learned during the teenage years and include the following: •••• Managing finances •••• Handling transportation (driving or navigating public transit) •••• Shopping •••• Preparing meals •••• Using the telephone and other communication devices •••• Managing medications •••• Housework and basic home maintenance Together, ADLs and IADLs represent the skills that people usually need to be able to manage in order to live as independent adults. Doctors, rehabilitation specialists, geriatric social workers, and others in senior care often assess ADLs and IADLs as part of an older person's functional assessment. Difficulty managing IADLs is particularly common in early Alzheimer's and other dementias. Assessing IADLs can help guide a diagnostic evaluation, as well as determine what kind of assistance an older person may need on a day-to-day basis. As visual discrimination is involved in these activities, a visually impaired person cannot learn the same on his own. Through his other senses, he may get an idea of what is going on but he cannot learn the exact procedure. It has been

175 observed that loss of confidence associated with the loss of vision retards the daily living skills of such a person. At the same time, lack of opportunity and environment are also the major causes of restricted performance of such activities. Thus the major objectives or needs of imparting training in daily living skills should be to: •••• enable him to carry out his day to day activities with the least possible external assistance and with safety; •••• help him to be self-sufficient in all functional activities; •••• in still confidence to enable him to be socially integrated; •••• develop healthy personal and family relationships; •••• learn scientific management of self and home; •••• become aware of safety precautions to be taken in the home; •••• become a well groomed person; •••• reduce dependence upon the care-takers; •••• expedite comprehensive rehabilitation including economic independence; and •••• develop a positive self-image. Acquisition of daily living skills refers to a child's ability to complete daily adult activities, including: •••• Caring for personal health •••• Managing money •••• Taking care of personal needs •••• Preparing food •••• Caring for clothing •••• Shopping •••• Maintaining a living space •••• Managing time Evaluating the skills the child already has is the first place to start. Begin by assessing child's skills in the following areas and then target areas to work with your child to increase his or her level of independence:

176 •••• Gets self up in morning •••• Maintains personal hygiene/grooming •••• Selects appropriate clothing •••• Dresses self independently •••• Cares for personal hygiene and grooming •••• Manages time effectively •••• Meets schedules/attends appointments on time •••• Performs routine household cleaning •••• Does laundry •••• Prepares simple or pre-packaged foods •••• Manages money effectively •••• Selects/shops for appropriate foods •••• Finds appropriate source for varied consumer goods •••• Dials telephone numbers •••• Practices personal safety rules in all environments Appropriately asks for assistance when needed Occupational therapists are often involved in helping students learn daily living skills. Activities of daily living (ADLs or ADL) are a term used in healthcare to refer to people's daily self-care activities. The concept of ADLs was originally proposed in the 1950s by Sidney Katz and his team at the Benjamin Rose Hospital in Cleveland, OH and has been added to and refined by a variety of researchers since that time.[1] Health professionals often use a person's ability or inability to perform ADLs as a measurement of their functional status, particularly in regard to people post injury, with disabilities and the elderly.[2] Younger children often require help from adults to perform ADLs, as they have not yet developed the skills necessary to perform them independently. ADLs are defined as "the things we normally do... such as feeding ourselves, bathing, dressing, grooming, work, homemaking, and leisure." [3] A number of national surveys collect data on the ADL status of the U.S. population. [4] While basic definitions of ADLs have been suggested, what specifically constitutes a particular ADL for each individual may vary. Adaptive equipment and devices may be used to enhance and increase independence in performing ADLs.

177 Basic ADLs Basic ADLs consist of self-care tasks that include, but not limited to: Functional mobility, often referred to as transferring (moving from one place to another while performing activities) For most people, functional mobility is measured as the ability to walk, get in and out of bed, and get into and out of a chair? the broader definition above is useful for people with different physical abilities who are still able to get around independently. Bathing and showering (washing the body), Dressing, Self feeding (not including cooking or chewing and swallowing), Personal hygiene and grooming (including brushing/ combing/styling hair), Toilet hygiene (getting to the toilet, cleaning oneself, and getting back up) One way to think about basic ADLs is that they are the things many people do when they get up in the morning and get ready to go out of the house: get out of bed, go to the toilet, bathe, dress, groom, and eat. Although not in wide general use, a mnemonic that some find useful is DEATH: dressing/bathing, eating, ambulating (walking), toileting, hygiene. Instrumental ADLs Instrumental activities of daily living (IADLs) are not necessary for fundamental functioning, but they let an individual live independently in a community: Housework, Preparing meals, Taking medications as prescribed, Managing money, Shopping for groceries or clothing, Use of telephone or other form of communication, Transportation within the community A useful mnemonic is SHAFT: shopping, housekeeping, accounting, food preparation/meds, telephone/transportation. Occupational therapists often evaluate IADLs when completing patient assessments. The American Occupational Therapy Association identifies 12 types of IADLs that may be performed as a co- occupation with others: Care of others (including selecting and supervising caregivers), Care of pets, Child rearing, Communication management, Community mobility, Financial management, Health management and maintenance, Home establishment and maintenance, Meal preparation and clean-up, Religious observances, Safety procedures and emergency responses, Shopping Role of physical therapy Physical therapists use exercises to assist patients in maintaining and gaining independence in ADLs. The exercise program is based on what components patients are lacking such as walking speed, strength, balance, and coordination. Slow walking speed is associated with increased risk of falls. Exercise enhances walking speed, allowing for safer and more functional ambulation capabilities. After initiating an exercise

178 program it is important to maintain the routine otherwise the benefits will be lost. Exercise for patients that are frail is essential for preserving functional independence and avoiding the necessity for care from others or placement in a long term care facility. Assistance Assisting in activities of daily living are skills required in nursing and as well as other professions such as nursing assistants. This includes assisting in patient mobility, such as moving an activity intolerant patient within bed. For hygiene, this often involves bed baths and assisting with urinary and bowel elimination. Evaluation of ADLs There are several evaluation tools, such as the Katz ADL scale, the Older Americans Resources and Services (OARS) ADL/IADL scale, the Lawton IADL scale and the Bristol Activities of Daily Living Scale. Most models of health care service use ADL evaluations in their practice, including the medical (or institutional) models, such as the RoperLoganTierney model of nursing, and the resident centered models, such as the Program of All Inclusive Care for the Elderly. 3.5.2 Techniques of Teaching Age Appropriate Daily Living Skills Activities of Daily Living (ADL) comprise everything entailed in human life and relationships. These are the basic activities necessary during an ordinary day. There are hundreds of activities which a person performs from the moment he wakes up in the morning till he goes to sleep at night. Sighted persons normally learn to perform these activities by themselves by observing other persons. A large part of daily living activities are learnt by observation and imitation. The area to consider when wanting to introduce Activities of Daily Living (ADL) into either a resource classroom setting or itinerant program is a foundation of Consistency and Developing Memory Skills. These skills are also fundamental in Planning and Organization. Consistency includes: ●●●● The student is the one to determine the placement of items; some guidance may be offered to ensure that the student is not making more work for themselves by having to crisscross back and forth across the work area. Example, when doing dishes in a double sink, if all the dishes, to be washed, are setting to the right side of the sinks, then the wash water should be the first sink to the left, then the drying rack should be in the left-hand sink. Remember to be aware of and work

179 toward the student's dominant side. (left or right handed)The student should also be responsible for retrieving the desired object, not family, teacher aides, other classmates, or the teachers themselves. •••• Developing the memory through practice. If the student has some memory problems (not cognitive impaired) then teaching some memory techniques can work. If a student does have some cognitive impairment then make use of tape recorders, braille or large print lists placed in obvious places to assist with the established systems. Planning and organization skills are not something that need to occur only at school. The organizational systems should begin at home. •••• Understand and arrange for appropriate lighting for the low vision individual. Levels of Labeling Categories: i. Permanent--appliances: microwaves, washers and dryers, stoves, etc. ii. Reusable--kitchen supplies: canned goods, spices, different bottle shapes (ketchup versus mustard) similar shaped bottles, use olfactory to distinguish, such as salad dressings. iii. Disposable--quick, one time read: post-it notes for large print or braille where it needs to be only used for short time, or one reading iv. Tactual--for the non -reading student, use recognizable shapes to specify items, such as a shapes, circle, square, or triangle. Rubber bands, held in place with masking tape, even if bands break the tape holds them in place for counting purposes. •••• Home Systems: 1. Clothing--Group long sleeve shirts, short sleeve shirts, casual clothes, and dress clothes into separate parts of the closet. Label the clothes with some tactual means of identification that will go through the laundry safely and intact. and intact. For example, sewn-in braille colour tags, crimped safety pins in a specific design, sewn-in number of buttons that means blue, red, yellow, etc., with a secondary means of knowing whether there are stripes or patterns to the outfit. 2. Sock locks--Means of keeping pairs of socks together, during washing, or socks that are tactually identifiable from other socks, minimize the number of different colour socks. If a student has memory problems with these systems, the above mentioned taped, brailled, or large print list can be placed in an adjacent location,

180 taped to the wall, on a shelf in the closet or in a drawer in the room. This establishes a pattern of consistency. •••• Food and canned goods: Labelling foods, canned goods have the opportunity to have reusable labelling systems. For instance, a rubber band, a brailled strip of paper with a hole punch, will allow a student to identify items in the cupboard, use them, remove the label and place it in a box for later use. This placing in a box also provides a grocery list. The labels can be taken to the grocery store and provide the list and place the label on the items as they go into the basket. This way when they return home it is already labelled while at the store. •••• Planning is in large part an exercise in problem solving. The first step in problem solving is to realize that you have a problem, then to determine all the options that might solve the problem. Once all the options have been identified, then the options can be reviewed for disadvantages and advantages. Once these have been reviewed there are usually several final choices for one to choose from. This latter part is important for if another person is involved in solving this problem, they are always more receptive in working out the problem if they have choices. This system has been named SODAS. Identifying the problem is the Situation Options is the brainstorming phase, Disadvantages and Advantages is obvious and Solutions are the choices for solving the problem. •••• Curriculum Connections: integrate the curriculum with the various ADL skills. There will be overlap between the various areas. Ø Math: 1. Measuring: reading recipes utilizes fractions, 1/4 cup, teaspoon, etc., plus, literary or Nemeth Code, reinforcement. 2. Setting timers teaches 15 minute versus quarter hour, time telling skills, etc. 3. Time and distance: Planning for the grocery store trip, how to get there, how long it will take to get there, learning and understanding bus schedules if applicable. Coordinate with O&M instructor. 4. Budgeting: figuring costs, taxes, learning about product brands, coupons, use of abacus, talking calculator, etc. creating a check register or use of a talking check book program. 5. Technology: shopping online, Pea Pod, using the calculator of a portable electronic note taker.

181 Ø Science: 1. Cleaning supplies: teach how to use for directional sprays, what is dangerous if ingested, gets into eyes, organized patterns, circular or overlapping patterns, etc. Natural cleaning supplies, such as vinegar, baking soda, club soda, etc. can be a good alternative. 2. Effects of temperature on foods, best storing methods, melding of long kept foods. Ø Reading: 1. Reinforce braille reading and writing skills: create the menu, reading and writing the recipes, reinforces literary or Nemeth Code. (Use thermoform paper to write recipes so that any cooking materials can be washed off.) 2. Use technology to search for recipes either on a CD or Internet. 3. Creating the shopping list braille or large print reinforces spelling skills. 4. Use of low vision aids and appropriate lighting for reading stove temperature, recipes, etc. Ø Social Studies: 1. Different Nationalities: research about different cultures, their foods, Holidays through the year as themes for the cooking experiences. 2. Repetition of activities: slicing, dicing, peeling and paring of vegetables, remember one experience is not likely to make the students skilled in the activity. 3. Technology: research through CD based books, or the Internet. Ø Language Arts: 1. Spelling and grammar: Involve the students in the writing of letters, requests for small grants, the thank you notes once a grant is secured. (See section on funding.) 2. Signature and handwriting: This for writing checks, signing for credit cards, etc. (Begin this at the same time sighted students are learning their letters and cursive, much easier to convince at that age, then later.) Ø Preparation options: 1. Coordinate with the Home Economics department to make use of the kitchen. 2. Electric skillet: can be done in the resource classroom, can prepare a wide range of dishes in this from scrambled eggs to hamburgers, to chicken, etc.

182 3. Microwave cooking: This offers a wide range of choices and can meet different student skill levels; it will incorporate many of the above skills as well. 4. Toaster ovens or specialty devices, like pizza makers, cookie ovens, George Foreman Grills, etc. (see funding options for more information). ●●●● Eating Skills: This doesn't fall under any specific traditional educational curriculum, but is a critical skill to possess. Once the cooking has occurred in a classroom the students need to have experience with cutting meat, spreading condiments, etc. Play Dough can be used as the on-going cutting experience, spreading butter on a cracker, etc. ●●●● Restaurant excursions: Sit down restaurant, not fast food. Can order off menu, no finger foods, can order hamburger, but must take off bun and use knife and fork. Budgeting for their meals, including tax and tip (math skills). ●●●● Menu reading and understanding: this could be in braille, using low vision aids, or in some cases using access technology to read the restaurant web site menu, prior to arriving at the restaurant. (This may involve VI teacher securing the print menu prior to excursion and preparing it in braille ahead of time.) Coordinating with the O&M instructor to plan the bus, train, or walking route with appropriate students. While the others, need to learn to negotiate the cluttered environment of the appearance of randomly placed tables and chairs. Low vision students dealing with the potentially inadequate lighting for locating a table and reading menus. This could then bring out the advocacy skills of a student to request assistance of the restaurant staff for sighted guide. ●●●● Technology: research for local addresses, through the phone, web site, or phone book with a Video magnifier. Use the technology to write the request, printing out in braille or large print for proofreading purposes and use of spell checker. Involve the parents whenever possible to observe how the students learn the different skills for follow up at home. ●●●● Itinerant Programs: Many of the same content listed above can happen in an itinerant program, but the difficulty comes when trying to take the time out of the regular class day. Some VI teachers arrange for a specific time in the day where they have the student outside of the regular classroom when some of these activities could occur. Coordinating with the home economics teacher for the use of the kitchen or at least part of it.

183 Thus activities of daily living include all those activities which people do every-day. Training a visually impaired person in these activities would enable him to become self-reliant, independent and more confident in his routine activities.

Although these activities are not an end in itself, these certainly are a very essential means toward complete, meaningful and comprehensive rehabilitation. ●●●● Daily Living Devices These devices can be further classified into the following five categories: ●●●● Clocks and Watches ●●●● Games and Puzzles ●●●● Sports ●●●● Kitchen Equipment ●●●● Personal Devices

Clocks and Watches: Alarm Clock: A standard alarm clock adapted for the use of the visually impaired.

It has strengthened hands and an open plastic dial having the hour positions indicated by two raised dots at the 3, 6, 9, 12 positions

and

single dots at the remaining hours.

Pocket Watch: A hunter watch, the hinged cover of which opens when the winding knob is depressed. Fitted with strengthened movements and dots as mentioned earlier. Ringer Timer: A one-hour ringer, in streamlined plastic case for timing any operation where an audible reminder is required. Each five minute period is indicated on the embossed setting dial by two dots and the first quarter hour is additionally marked to show the individual minutes.

Talking Time: This is an electronic watch as well as alarm clock fitted with an electronic device which announces the time whenever the knob is pressed. It is possible to set time, date, day and alarm etc. All the settings are audible in signals, it is thus possible for a visually impaired person to do the setting himself. The most popular brands are Sony and Sharp. In India,

Games and Puzzles: Playing Cards: Superior quality standard playing cards with the reverse embossing in standard Braille on the top left corner.

184 Chess: A wooden board with the black squares raised and all the squares drilled in the centre for the reception of the pegged chessmen. Holes are provided at each end for pieces not in play. The pieces are of uniform height, the white having a point at the top to distinguish them from the black. Dominoes: Made of plastic and having raised black dots on a white background with black inset pieces on the reverse. These dominoes are ideal for players with low vision also.

Brahma Puzzle: The puzzle consists of three pegs on a wooden base and eight discs of different diameter each with a hole in the centre. The purpose is to transfer all the discs from the peg to another without allowing any disc to be placed over a smaller one. Audible Ball: Made of strong good quality rubber in which holes have been punched. Small metal balls are inserted for creating sound enabling the

ball to be located when in play.

Draught Board: A wooden board with sunken playing squares. The colours of the men are distinguished by size. Pieces of double thickness are used as kings. A variety of other games as listed below have also been adapted for the visually impaired: Bezique Maker, Bridge Scorer, Lexicon, Happy Family, Whot, Patience Board, Chess Clock, Jigsaw Puzzle, Electronic Ball, Beetle Game, Centre-peg, Dice and Dice Cup, Nine Men's Morris, Scrabble, Unilock Word Building Device,

Tic-Tac-Toe, Checkers Set, Rattle Bells.

Sports: Football, Basket Ball and Soccer Ball: These

are equipped with a small electronic beeper which is battery powered and emits a compact sound. The beeper is held within a moulded cavity designed for easy access to 'on & off' switch.

Stick

Walking: The ordinary strong bamboo sticks with foot rest at a height of 30 Cms from the ground can be used for training the visually impaired in stick walking. Swimming: is also emerging to be a popular sport among visually impaired persons. The normal swimming pool with sound indicators on the sides can be used for training them in swimming.

Athletics: The normal track with some precautions and safety measures can be used for training the visually impaired in race, shot put, javelin throw, bag-walk, musical chair, hit the target etc.

185

Table Tennis: has become a popular in-door game for the visually impaired in many South-East countries.

The normal table tennis table with some modifications in the net and the sides can be used for the purpose.

Kitchen Equipment

Equipment Adapted for the Visually Impaired: i. Egg Poaching Ring: An adaptation of standard egg ring to enable visually impaired persons to fry or poach eggs, and to serve them easily. It has a handle vertically attached to the egg ring. ii.

Measuring Jug: A heat proof clear glass jug of standard capacity with raised markings inside to indicate the specific volume. With the use of fingers, a visually impaired person can measure the volume. iii. Bread Cutting Box: An adjustable slide is fitted to gauge thickness of the slice. It enables visually impaired persons to cut the loaf of bread into even slices using a standard bread knife. iv. Liquid Level Indicator: A simple electronic device, powered by a battery, enables a visually impaired person to ascertain the level of liquid being poured into a cup. It emits a sound signal when a particular level is reached. v. Self Adhesive Labels: These plastic labels can be embossed with Braille and used for labelling a wide variety of articles. vi. Open Market Products with Special Relevance for Use by the Visually Impaired: Tomato Slicer, Chilly Cutter,

Kitchen Helper, Vegetable and Fruit Scraper, Multi-purpose Scraper, Egg Beater-cum-Juicer, Gas Lighter, Milk Cooker, Pressure Cooker, Jar & bottle opener, Pan holder.

Personal Devices i. Sound Beacon: This pocket size electronic device emits a sound which can be varied from a loud continuous whistle down to low intermittent beeps at various rates. It is generally used as a homing device. ii. Notex: It consists of a rectangular base and flaps made of high-density polythene hinged together. It differentiates Indian currency notes of different denominations. It considers length and breadth of a currency note for its differentiation.

186

iii. Magnets: Round, square and U-shaped magnets for picking up pins, small nails and other iron or steel objects. iv.

Signature Guide: A template to guide the visually impaired persons in placing signature in proper position on letters, cheques etc. v. Address Templates: Made of cardboard with four raised lines to guide a visually impaired person to write his address on Inland letters and envelopes. vi. Light Probe: Full function light detector may be adjusted for desired sensitivity to light. vii. Location Finder:

Find your

house, apartment, or office easily with portable, light weight location finder. A siren, attached outside location, will sound on pressing transmitter attached to a key chain.

viii. Other Personal Devices: The American Foundation for the Blind and Maxi Devices are supplying a variety of personal devices for the visually impaired persons as listed below. These are so far not available in India.

Like-

Thermo Voice: announces temperature, Talking Blood Pressure & Pulse Monitoring Kit, Becton Dickinson Magni Guide: for accepting barrel of insulin syringe, Insulin Needle Guide, Talking Blood Glucose Monitoring Kit, Big Print Address Book, Talking Wallet, Locklid Saucepan, Weight Talker, Keyfinder, Clothing Identifiers, Tactile Braille Signs, Eye-Ease Eye drop Guide, Medicine Spoon ❖❖❖❖❖

Training Strategy Due to lack of visual perception as well as discrimination, it is difficult for a visually impaired person to learn daily living skills on his own. As most skills are of a routine nature, he does not need to learn any special techniques for performing these skills. However, it is essential to train him for the particular procedures involved in performing the activity. In swimming, for example, he has to follow the same steps as a sighted person but may need to be given special training in safety matters. Many times, special techniques or special equipment or adaptations may help him to perform certain activities more proficiently. These techniques or adaptations make use of other senses of touch, hearing, and

taste etc. for his convenience. By using a Talking Clock, for example, he may know the time, day and date as conveniently as a sighted person.

187

Procedure for Designing the Daily Living Skills a. Observe daily living skills of sighted persons of different age groups. b. Identify the difficulties faced by a visually impaired person in performing such activities and learning the skills. c. Develop specific procedures for each skill with suitable modifications. d. Consider the following aspects concerning visually impaired persons while evolving the training schedule: individual felt needs, physical potentials, age, age at the on-set of visual impairment, family background, economic status and occupation, environment, and past experience e. Explain the procedure followed by sighted persons in performing a particular activity to visually impaired persons. f. Impart relevant training in orientation and mobility associated with the effective performing of a particular activity. g. Supplement the skills with appropriate assistive devices and adaptations. h. Incorporate an in-built system of monitoring and evaluation of the training programme. i. Adopt a system of follow-up for sustaining the abilities to perform the activities. Specific Rules for Teaching Daily Living Skills

a. Gather the relevant and needed following items before initiating the training: All materials, Equipment Special assistive devices and adaptations

and Embossed diagrams and tactile adaptations b.

Perform task analysis for evolving the proper sequence; deciding the procedure of performing the activity; and finalizing the lay-out and positioning of the material and equipment. c. Orient the person regarding location of the materials; procedure of taking and replacing the same; hand co-ordination; sequence of various operations; safety measures; use of equipment and adaptations; and safety measures. d. Ensure appropriate use; safety of the individual; no damage to equipment; and least possible wastage.

188 e. Supervise during the performance of the procedure and provide instructions whenever essential. f. Follow-up, evaluate and appreciate good performance. Example: Preparing a Cup of Tea

Step 1. Collecting the Material and Equipment

a. Material: milk, sugar, water and tea leaves

b. Equipment: stove/cooking gas and kettle/utensil, cup, strainer, table spoon

c. Adaptations (optional) for: •••• measuring volumecan be easily developed locally kitchen utensils can be used •••• indicating boiling liquid can be developed on the lines of pressure milk boiling pot by sound •••• sugar measurecommonly used spoon in the house

Measuring devices are available abroad but are very expensive and not advisable for developing countries. It is best to teach how to use utensils and other Items which are used by the general population. Thus adapting techniques to suit visually impaired person would be necessary. Most adapted material like measuring and pouring devices (to name a few) are generally expensive and not easily available, the majority of visually impaired persons would have to learn to utilize the existing and available equipment after careful sensory training.

Step 2. Task Analysis for Evolving the Procedure

On task analysis, the activity of preparing a cup of tea can be divided into following tasks:

Pouring Water

1. Lift and scrub kettle/utensil
2. Fetch water
3. Measure water
4. Pour water into kettle/utensil

Making Fire

5. Locate stove/gas stove
6. Lift match box/gas lighter with one hand
7. Hold match box/gas lighter in one hand
8. Pour kerosene by pressure in case of stove or switch on gas stove
9. Strike match or press lighter
10. Make fire by holding match or lighter near the stove/gas stove

Boiling

11. Lift kettle/utensil
12. Position the kettle/utensil on stove/gas stove
13. Cover the kettle/utensil with the lid

Adding Tea Leaves

14. Lift the container containing tea leaves
15. Open the lid
16. Fill a spoon with tea leaves
17. Remove the lid when water is boiling and add tea leaves
18. Replace the container back to its original position

Adding Sugar

19. Lift sugar measure/ If it is not available, lift the sugar container
20. Add sugar by tilting the measure (or from the spoon)
21. Replace the sugar measure (or sugar container) to its original place

Adding Milk

22. Take milk pot
23. Measure the desired quantity using a measure or a cup
24. Pour milk into the utensil/kettle
25. Cover the utensil/kettle
26. Replace the milk pot to its original position

190 Pouring Tea

27. Wait for the tea to boil
28. Switch off the stove/gas stove to put off fire
29. Wait for two minutes
30. Bring tea-pot near the stove
31. Remove lid of the tea-pot
32. Lift strainer and place it on the tea-pot
33. Remove lid of the kettle/utensil
34. Lift the kettle/utensil off the stove/gas stove using cloth or clamp
35. Pour tea into the tea-pot through the strainer
36. Cover tea-pot with lid
37. Place the kettle/utensil, strainer and clamp in the sink for washing

38. TEA is READY for serving.

Serving Tea

39. Hold handle of the tea-pot in the right hand
40. Touch the cup with left hand and keep first finger on outer side of the top of the cup
41. Lift tea-pot with right hand and bring the pouring point over the cup.
42. Start pouring till first finger of the left hand feels hot.
43. Leave the tea-pot back with right hand, lift cup with right hand itself and drink tea.

Step 3. Time Study for Deciding Location of Various Materials and Equipment

Consider the following pre-requisites of efficient production performance while evolving the most appropriate location pattern:

- a. All materials and equipment should be within arm's length
- b. Left hand should move clockwise and right hand anti-clockwise while lifting materials and equipment etc. and in the reverse direction while keeping it back.

191 c. Positioning should be according to sequence of the tasks to be performed. The kettle/utensil, for example, as required first should be at the left extreme; and water as required next should be on the right extreme

- d. Safety of the person should be ensured while performing the activity
- e. Overlapping and criss-crossing of materials and equipment should be avoided. Based on time study, task analysis and other principles of production and operations management, the location pattern as given in the figure may be evolved.

Step 4. Orientation •••• explain location of materials and equipment to a visually impaired person •••• enable him to touch all these things •••• explain him the relative positioning of these things in the context of the entire room and his own self.

Step 5. Explaining the Procedure •••• explain all 43 tasks involved in the process •••• explain the sequence of the tasks •••• explain the need for following the sequence correctly, safety measures and likely eventualities. •••• explain the procedure for measuring water, sugar and tea-leaves •••• explain the procedure of pouring hot liquid

Step 6. Performing the Activity •••• supervise while a person is performing the tasks •••• instruct him as and when required •••• advise him to repeat the task whenever correct sequence is not understood or being followed •••• follow-up the process.

Hand Movement: The hand coordination based upon the above noted task analysis, positioning of equipment and materials and sequence of tasks in case of preparing a cup of tea is as listed below:

192

Task No. Hand Activity
 1. Left Lift the kettle/utensil
 2. Both Measure and pour water
 3. Left Lift match box/gas lighter
 4. Both Light the stove/gas stove
 5. Left Lift the lid and cover kettle/utensil
 6. Right Lift tea-leaves container
 7. Both Add tea leaves to kettle/utensil
 8. Right Lift stirring spoon
 9. Left Lift sugar measure/container
 10. Right Add sugar to kettle/utensil
 11. Right Measure and pour milk
 12. Left Lift tea-pot
 13. Right Lift strainer
 14. Both Position tea-pot with strainer on top
 15. Right Lift kettle/utensil
 16. Both Pour tea into

the

tea-pot
 17. Right Place kettle/utensil, strainer in the wash basin
 18. Left Lift tea-pot
 19. Right Pour tea
 20. Right Returning tea-pot to its position
 21. Right Lift cup and DRINK tea.

Step 7. Follow-up and evaluation in terms of
 •••• correct sequence
 •••• convenience in handling equipment and materials
 •••• pouring of tea leaves, sugar, milk or tea etc.
 193 •••• correct measurement of materials
 •••• speed of handling the tasks
 •••• confidence while performing tasks
 •••• any unnecessary delays, confusion, criss-crossing,
 •••• over lapping of tasks and collision of equipment " uniformity in operations and sequence when the same activity is repeated
 By following this procedure, activities of daily living, self-care skills and systems of home economics can be modified suitably to enable a person to perform the same independently. "

Training Content To enable a visually impaired person to be independent in the activities of daily living and home economics, training should be imparted in the aspects described below. The activities may be adapted to suit the needs of visually impaired persons of rural and urban areas. The principles are the same but minor modifications may be necessary.

Personal Care
 a. Hygiene •••• bathing •••• care of hands and feet •••• cleaning of ears •••• nail cutting •••• oral hygiene: manage toothpaste, brush teeth •••• personal hygiene
 b. Grooming •••• combing and care of hair •••• dressing and undressing •••• shaving, using facial cream •••• skin care, applying cosmetics •••• female grooming and hygiene

194 •••• using hair oil, cosmetics
 c. Social Graces •••• social manners, etiquette, courtesy •••• table manners, eating habits with fingers, spoon etc. •••• style and mode of dressing •••• postures while sitting, standing and talking •••• gestures •••• gait •••• socializing, art of conversation
 d. Toilet Activities
 Cooking Skills
 a. Orientation of •••• kitchen equipment, utensils, knives •••• weights and measures and modifications in techniques •••• special adaptations •••• grains, pulses, vegetables, flour, spices and provisions •••• different parts of stove, fuel, fire place •••• gas lighter, match box
 b. Preparatory Operations •••• cutting, slicing, peeling, pouring •••• grinding, mixing, kneading, grating •••• washing, cleaning, soaking, scrubbing •••• sieving, filtering, straining •••• rolling bread and roasting •••• boiling, frying, baking •••• making fire, lighting stove or cooking gas •••• operation and care of stove/gas stove

195 •••• setting curd, preparing butter milk •••• steaming and pressure cooking
 c. Serving Food •••• taking out food in serving bowls •••• setting dining table or arranging on floor •••• putting food on dining table/floor •••• following clockwise method of putting food in plates •••• serving water •••• removing bowls, plates and cleaning table
 House Keeping Skills
 a. Cleaning •••• sweeping, dusting •••• washing, scrubbing, mopping floor
 b. Care of Furniture •••• dusting •••• washing of upholstery •••• wiping of table tops •••• keeping furniture at fixed locations •••• hanging curtains
 c. Laundry •••• sorting, washing, drying •••• folding, ironing, proper stacking •••• mending, stitching, buttoning, darning
 d. Washing Utensils •••• sequence in scrubbing and washing •••• use of cleaning powder and scrubber •••• disposing off waste

196 •••• drying utensils •••• replacing utensils at pre-determined locations •••• special care of crockery
 e. Bed-making •••• location of cots •••• adjusting of mattresses •••• spreading of bed spreads •••• positioning of pillows, blankets and bed sheets
 Home Economics
 a. Money Management •••• currency identification, coin counting •••• safe keeping of money •••• budgeting for the month •••• simple account keeping •••• savings and investment •••• maintaining and operating a bank or postoffice account •••• depositing or withdrawing money •••• signing of cheques •••• knowledge about interest
 b. Time and Energy Management •••• time and routine activity planning •••• leisure time planning •••• work simplification techniques •••• process of cooking, heating water and lighting for energy conservation
 c. Furnishing the Home •••• selection and arrangement of furniture, furnishings and decoration articles •••• proper lighting and ventilation

197 ••••• proper placing of calendars, pictures, idols and other decorative articles ••••• positioning of wall clock and alarm clock d. Shopping Techniques ••••• quality of products ••••• types of shops and their location ••••• system, period and frequency of buying ••••• benefits of bulk buying ••••• awareness of mal-practices in faulty weights and measures; deceptive packaging and adulteration ••••• consumer rights and responsibilities ••••• method of using shopping bags ••••• sequence in stacking of items in the bag e. Using Appliances ••••• electric switches, plugs, fan regulators ••••• telephone ••••• call bell ••••• oven, refrigerator, toaster, mixer, geyser, pressure cooker ••••• cassette player, radio, television ••••• shaver f. Care of the Home ••••• sweeping and mopping floors ••••• repair & maintenance of doors, windows, furniture & fixtures ••••• proper placing of furniture, TV, other appliances etc. ••••• keeping doors and windows properly closed or opened to avoid protruding shutters ••••• white-wash, painting of walls etc. ••••• polishing, painting of doors, windows, furniture & fixtures ••••• proper arrangement and parking of vehicles ••••• keeping movement areas free of obstructions.

198 ••••• Training in Individual Activities Bathing techniques are the same for both sighted and the visually impaired. However, training in following aspects should be provided: ••••• Orientation of the bathroom or bathing place, hanging clothes and towel, place for keeping soap, bucket, tumbler etc. ••••• method of fetching water and its source ••••• safety precautions ••••• steps to be followed. Brushing Teeth techniques are the same for both sighted and the visually impaired. The main difficulty may be applying tooth paste on the tooth brush. The following steps may be followed for this purpose: ••••• Hold brush in the left hand with bristles upward between the thumb and the forefingers. ••••• Open the lid of the tooth paste with the thumb and the first finger while holding the same in the right hand ••••• Hold tooth paste tube in right hand and place the opening at end of the bristle ••••• Squeeze the tube so that tooth paste comes out and move it along the bristles taking care that the tooth paste does not fall on clothes or the ground. ••••• Replace the cap while holding the tube in right hand and replace the tooth paste to its original position. ••••• Shift the brush to the right hand and rinse the bristles with water ••••• Brush the teeth by moving the bristles up and down over the teeth and gums ••••• Wash the brush while holding the same in right hand and replace it to its original position ••••• Use left hand for taking water to the mouth for gargling and repeat it twice. Shaving technique is the same for both sighted and the visually impaired. However, the latter should be slow, more careful and observe the following precautions: ••••• Double-edged safety razor is more safe ••••• Downward movement of razor is advisable and the same pattern to be followed every time

199 ••••• Check with the hand if all areas of the face have been shaved properly ••••• Electric shaver is safe and convenient but very expensive Washing Clothes ••••• Gather material: soap, detergent, tub, brush, dirty clothes etc. ••••• Organize the material: place tub in the centre, dirty clothes on the left hand side, soap, detergent on the right hand side and source of water supply should be above the tub or nearby ••••• Apply soap on clothes, rub gently and soak in the tub ••••• Remove soap by rinsing clothes in water ••••• Squeeze and wring the clothes to remove water ••••• Clothes should be dried by spreading on a clean place or by hanging on a clothes-line Identifying Clothes ••••• By the material they are made of ••••• By design, tailoring style, pattern etc. ••••• By special markings in braille or otherwise which can be identified by touch ••••• By stacking at a particular place in a particular pattern Money Identification Coins: Coin /Paise Identification 5 Square 10 round with deep scallops on sides 20 Hexagonal 25 round, very thin, one centimetre diameter 50 perfect circle with plain circular boundary One Rupee perfect circle, bigger and thicker than the 50paise coin, circular boundary has a all central round groove

200 Currency Notes: It is generally difficult for a visually impaired person to identify the currency notes. In India, currency notes of one, two, five, ten, twenty, fifty and hundred are common. The rupee one and two notes are almost of the same size. Other currency notes are bigger. These notes can be identified by using the following methods: a. Notex: is a device developed by the NAB-Louis Braille Memorial Research Centre. It holds the currency notes in two flaps and the same is identified by the notches on the upper flap. b. Folding around the Wrist: This method is advocated by the officials of the National Association for the Blind, Rural Activities Committee. The visually impaired person can be trained to identify a currency note by folding it around his wrist and then determining the denomination by the extra length after the first fold. The width of the note is also considered. c. Spreading along the Palm: In this method the currency note is spread on the palm of the left hand from the wrist downward. The denomination of the note is determined by the point on the fingers at which the other end touches. The width of the note is also considered. d. Thickness of the Note: may also enable a person to identify the currency notes. The crispness is also considered. In case of old currency notes, this method may be misleading. Special Dot on Rs. 500 Note: The Rs. 500 currency note introduced during 1999 carries a round embossed dot at the periphery on the lower side of smaller arm. A visually impaired person can identify Rs. 500 note by locating this dot through finger movement on the outer side. A visually impaired person has to develop his own individualized sense of recognition based on the above. No blanket approach is viable or advisable. Pouring Liquids Pouring liquids requires good eye-hand coordination. A visually impaired person needs proper training to overcome the limitation imposed by blindness. a. Cold Liquids •••• Hold the tumbler near the tip of the jug containing cold liquid •••• Place index finger inside the tumbler

201 •••• Pour liquid slowly till it touches the finger b. Hot Liquids •••• Hold the cup near the tip of the tea-pot containing tea •••• Place index finger on the rim of the cup •••• Pour liquid slowly till it is sensed that the cup is full: by feeling the steam on the index finger, by realizing that the outside of the cup is hot, by feeling the difference in the weight of the cup, by hearing the change in sound associated with filling of the cup to the brim Making Open Fire In rural areas, the most common mode of making fire is an Angithi, Chullahor open space covered by bricks and mud. •••• Clean the open space •••• Pour kerosene on cow-dung cake or a dry wood •••• Stack small wood pieces over and around the cow-dung cake with air gaps •••• Light a kerosene lamp - the lamp generally has a metal or glass bottle for storing kerosene and lid into which a wick is embedded. One end of the wick protrudes outside and the other is soaked in the kerosene. •••• Make fire by taking burning wick of the kerosene lamp near the stacked wood and cow-dung cake which has been sprinkled with kerosene •••• Remove wood pieces or other like objects from near the fire place •••• Keep on adding wood or cow dung cake as required •••• After cooking, put off fire using water •••• Check by moving hand close to ash that no livecoal or burning wood is left. •••• As far as possible, no inflammable material should be kept near the fire place Lighting a Stove •••• Pour kerosene using a funnel and a standard bottle for measurement. •••• Difference in sound or weight would in dictate when the stove is almost full. •••• Wipe away any spilled oil to make the stove safer.

202 •••• Clean the burner nozzle using the stove pin. •••• Pour kerosene in the cup below the burner. •••• Use a safety match for lighting. •••• Use stove lighting ring, which is easily available in the market, for lighting the stove. •••• Operate the pump two minutes after lighting the ring to vaporize the kerosene and activate the burner. •••• Sound of the burner indicates intensity of fire. •••• Release pressure to reduce intensity of the fire or to put it off. Lighting Gas Stove For safety, the gas regulator which is mounted on the cooking gas cylinder should always be switched off. The knob of the regulator should be turned anti-clockwise till it touches the lower circle of the regulator. The following procedure is recommended while lighting the cooking gas stove: •••• Check that the knob of the regulator is in off position •••• Check that the rubber tube is well connected at both the ends, i.e. regulator as well as gas stove ends. •••• Check that the knob of the gas stove is in off position. •••• First of all, twist the knob of the regulator clockwise till there is click sound. •••• Hold the gas lighter in right hand, keep its front part on the gas burner and keep the thumb on the lighter knob •••• With the help of left hand, move the knob of the gas stove clock-wise, only one step to slow position, to start the flow of the gas. •••• Simultaneously, ignite the lighter by pushing its knob by the use of thumb of the right hand. •••• Move the left hand little above the gas burner to ascertain where the gas starts burning. •••• There is "Bhuup" sound when the gas is lighted.

203 Precautions: ●●●● Always keep the lighter on the right side of the gas stove, preferably stuck to the wall at a arm's distance. ●●●● Keep the regulator in switched off condition when gas stove is not in use. ●●●● If there is a foul smell which indicates gas leakage, move the knob of the gas stove anti-clockwise and close the regulator also. ●●●● Do not make fire till the smell persists. ●●●● While lighting the stove, the knob of the gas stove as well as lighter should be operated simultaneously to prevent flow of un-burnt gas. Switching off the Gas Stove: The following procedure is recommended for this purpose: ●●●● Move knob of the gas stove with the right hand anti-clockwise till the lower end. ●●●● Take left hand on the burner to ensure that fire has completely disappeared. ●●●● Move the knob of the regulator anti-clockwise till there is click sound and upper ring of the regulator moves downward. Eating ●●●● Avoid serving food by keeping the meals plate on the ground, if possible ●●●● If dining table is not available, use a stool or a raised wooden platform (chowki) ●●●● It is easier for the visually impaired person to locate food if it is always placed at the same spot and served in familiar utensils ●●●● It is more convenient and desirable to prepare the plate with vegetables, rice, chapati etc. ●●●● Serve food according to the dial of a clock as indicated below: The following hours of the clock positioning of various items of standard Indian meals is recommended. It may be suitably modified according to the menu and the individual needs: ●●●● Water glass should be on the left hand side outside the plate. ●●●● Vegetable bowl should be on the left side outside the plate. ●●●● It is easy for a person to feel what food he is eating and how much, if he eats food with his fingers. 204 Clock Position Item 1-2 O'clock Sweet/dessert 3 " Chapatti(bread) 4 " Curd 5 " Gravy 6 " & Centre Rice 7-8 " Pulses 9-10 " Vegetables 11 " Pickles 12 " Salad ●●●● The proper way to hold and use a spoon and a fork is the same for both the sighted and the visually impaired. Generally the fork is held in the lefthand and spoon in the right. ●●●● The system of coordination of fingers is the same for both the sighted and the visually impaired. ●●●● It is essential to maintain a proper posture while eating. ●●●● The local manners and customs which are to be observed while eating must be taught to the visually impaired. First Aid a. Definition: It is the first help given to an injured person or to those taken suddenly ill before taking them to a health centre or hospital. b. Objectives: ●●●● to save life ●●●● to prevent injuries becoming worse ●●●● to help recovery c. Importance: Many a times, while performing activities of daily living, travelling, moving around or in the course of employment, a visually impaired person may injure himself. Particularly when moving in an unknown environment, he may

205 bump into some obstructions, walls, household articles, parked vehicles etc. At such time, immediate medical care may not be available. If he is trained in First Aid, he will be able to take immediate measures and prevent injuries from becoming worse. d. First Aid Kit: should contain the following: ●●●● Bandage ●●●● Cotton swab ●●●● Scissors ●●●● Antiseptic material like Dettol, safeguard etc. ●●●● Band-Aid ●●●● Brunel ●●●● Simple medicine like Analgine, Metacin etc. e. Illustration: First Aid in case of bleeding ●●●● Apply steady and very firm pressure directly over the bleeding ●●●● Make the injured person lie down ●●●● Lift up the injured organ ●●●● When the bleeding slows, apply a pressure bandage over a pad f. Training: During training in Activities of Daily Living, 2-3 lectures on First Aid should also be included. A local physician, or qualified health worker or the officials of the Red Cross may be invited for this purpose. The field staff in turn should train the visually impaired person in First Aid. He should be encouraged to keep a First Aid Kit in the house or at the place of work. ●●●●

Nature of Training in Activities of Daily Living in Indian Conditions Irrespective of the age of the person or the different customs or the different economic strata a person may come from, there are certain common basic daily activities for everyone. It is possible to do classification according to age groups for providing training in the activities of daily living. It is, however, essential to consider the following aspects while planning training in activities of daily living: ●●●● Specific felt needs ●●●● Family back-ground

206 ●●●● Past experience ●●●● Physical potentials, and ●●●● Educational background of the individuals. It has been observed that it is essential: ●●●● to provide training in natural settings as simulating conditions may not be result oriented; ●●●● to support such training with relevant training in orientation and mobility and sensory perceptions; ●●●● the training should be considered an integral part of all subjects taught to the visually impaired; and ●●●● in case of a visually impaired child, it is essential to train the parents in basic skills so that they may in turn teach these skills to the child when he is at home.

The training needs can be classified

according to age groups. Age Group 0-16 Years a. Personal Hygiene ●●●● bathing ●●●● toilet training ●●●● oral hygiene: dental care, brushing teeth, keeping brush at proper place ●●●● nail cutting ●●●● cleaning ears b. Grooming ●●●● care of hair ●●●● shaving ●●●● putting on clothes, buttoning them properly ●●●● wearing footwear c. Social Graces ●●●● holding of meals plate, eating without spilling food ●●●● positioning of glass, drinking cold and hot liquids

207 •••• use of spoon, if applicable •••• table manners, proper posture and gait d. Cooking Activities •••• lighting of stove, making fire •••• general cooking skills, cooking vegetables, pulses •••• preparing tea, coffee and boiling milk •••• rolling and roasting chapati •••• using frying pan, kettle, utensils •••• boiling of rice e. Preparatory Kitchen Activities •••• washing and cutting of vegetables •••• kneading dough •••• setting curd and preparing butter milk •••• preparing salad f. House-Keeping Skills •••• scrubbing and cleaning utensils •••• drying and stacking utensils •••• cleaning, dusting and mopping floor •••• washing clothes in the house, at the pond and the canal •••• adjusting house-hold things •••• making and folding bed and bed linen •••• positioning and removing cots g. Home Economics •••• currency identification •••• counting of coins and currency notes •••• safe keeping of money, maintaining accounts •••• understanding barter system

208 •••• preservation of grains etc. h. School Activities •••• understanding and proper upkeep of the school uniform •••• maintaining proper posture in the school •••• playing common games: stick walking, carom, chess, playing cards •••• keeping pocket money carefully •••• proper handling of school bag, books and stationery •••• memorizing poems, songs and lessons Working Age Group 17-60 Years The visually impaired persons of this age group are in the prime of their life. They are expected to be the earning members of the family. They must be economically rehabilitated. Hence, the training in activities of daily living must focus at enhancing their earning capacity and their integration into the mainstream of society. The training in activities of daily living which is provided to visually impaired persons in the age group 0-16, as listed earlier, should be provided to the persons in this age group also with the exception of training in school activities. The additional components of training for this age group are listed below i. Social Graces •••• social manner, etiquette and graces •••• posture while at work and while talking •••• polishing and maintaining of shoes •••• sense of dressing according to the occasion •••• skills of developing inter-personal relations j. House Keeping Skills •••• washing floor, covering it with cow-dung and mud •••• pounding and grinding grains and spices •••• cooking handling, proper keeping and preservation of food articles, pickles, spices and like materials •••• fetching water from the well and storing the same in pots

209 •••• making open fire •••• boiling pulses in earthen pots •••• washing utensils at the pond •••• taking care of the children and the elderly •••• threading needle, elementary darning and mending of clothes; stitching of mattresses, quilts, pillows k. Shopping Techniques •••• purchasing vegetables and provisions from a nearby market or the weekly rural market •••• verifying quality of vegetables and fruits •••• safe keeping of money at proper place in the house l. Economic Activities •••• going to farm independently •••• learning to perform economic activity in terms of local crafts, trades or agriculture operations •••• buying of raw materials and selling of finished products •••• performing of social obligations •••• taking care of domestic animals •••• feeding, grooming, milking and grazing of milch animals Age Group: 60 Years and Above Due to physical constraints, most of the persons in this age group can- not undertake laborious work. Thus the economic and production activities have a very limited scope. It is, however, desirable to plan for their social integration. It is essential to actively involve the family members in the training process as their assistance would be of utmost importance later on. The training components as listed for age groups 0-16 and 17-60 years may also be provided to this age group also with the exception of school activities, house- keeping and kitchen activities. The persons of age group 60 years and above should be provided additional training as regard: •••• method of offering prayer, performing worship at the local temple;

210 •••• meeting other aged persons at public places and exchanging views; •••• special aspects of toilet training; •••• taking medicines whenever required; •••• taking care of children and ailing family members; •••• assisting in the family occupation; •••• becoming active member of the senior citizen club; •••• assisting other family members in house-keeping, home economics and other daily activities; and •••• training children in personal hygiene, social graces, school activities and home economics. ••••

Special Tips for the Rehabilitation Functionaries a. It is necessary to explain the causes of visual impairment to visually impaired person and community to eliminate prevailing superstitions. If the visual impairment is incurable, the person must be informed accordingly. He must be convinced to accept his visual impairment. b. Win his confidence; motivate him to take personal and keen interest in the training programme. c. Plan training in orientation and mobility and activities of daily living according to : •••• felt needs of the individual; •••• his interests and aspirations; •••• his physical potentials and educational background; •••• past experience, age at on-set of visual handicap and existing level of performing these activities; and •••• in consonance with his family background, occupation and economic status. d. Have patience and help the visually impaired person to: •••• touch the materials and equipment; •••• understand procedures and implications of each task; and

211 •••• permit him to touch the body of the fieldstaff to understand motion of performingthe activity. e. Demonstrate to him a particular activity, wearing a blind fold, to convince him regarding: •••• usefulness of activity; •••• ease of performance; and •••• possibility of performing activity in the absence of sight. f. Counsel the family in the following respects: •••• He is normal otherwise •••• Lend him assistance in performing these activities •••• Active participation in the training process. •••• He is not a burden and through proper training he may become independent and contribute towards family earning •••• His social integration and economic rehabilitation is essential g. Encourage fellow students to •••• accept the visually impaired child; •••• help him in studies and daily routine; •••• not patronize or overprotect him; •••• encourage him to perform daily activities independently; and •••• participate in school functions and social get-togethers. h. Convince the school teacher to •••• pay personal attention to such a student; •••• make him sit in the front row; •••• speak out whatsoever is being written on the black board; •••• encourage his acceptance among fellow students; •••• involve him in all class-room, sport and other co-curricular activities; •••• make adjustments, be patient, and not get irritated;

212 •••• give him plenty of opportunity to repeat what he has learnt; and •••• encourage him to modify these techniques or activities to suit his requirement. i. Consistent follow-up and evaluation is essential for enabling him to internalize the activity in his daily routine. Most Important: The list of activities of daily living provided earlier must not be considered an exhaustive one. It merely provides guidelines to enable the field functionaries to think of many more such activities depending upon the individuals, their needs and the environment. 3.6

Sensory

Efficiency- Importance and Procedures for Training Auditory, Tactile, Olfactory, Gustatory, Kinaesthetic Sences and Residual Vision

Sensory

Efficiency: Sensory efficiency addresses the use of residual vision,hearing, and other senses to enable or enhance accessto the environment.

For example, learning how to use touch and smell ratherthan visual cues to identify one's personal possessionsor

one's location, or using hearing and the other sensesto identify people one knows without visual cues, fits intothis area.Sensory efficiency skills are valuable lifelongtools. Theyhelp youths who are visually impaired increase their useof auditory and tactual information in order to makesense of the world. Sensory efficiency also involveslearning how to use any remaining vision?for example,students with low vision need instruction in how, andwhen, to use residual vision.All children who are visually impaired need to learn howto use their auditory, tactual, and/or visual senses tomaximize their environmental access.

Sensory efficiency skills must be practiced throughmeaningful activities in the home and community, not justat school.

Taking this into account,

TVIs support

sensoryat

school. Taking this into account, TVIs support sensoryefficiency instruction across a range of stimulating andrelevant environments. For example, young children canuse monocular telescopes to look at distant objects in avariety of motivating settings: fast- food restaurants, malls, neighbourhoods, or playgrounds. Youths who are blindneed opportunities to use their sense of touch to learnabout a wide variety of objects and materials. Thesetactile skills are necessary to develop foundationalconcepts which are prerequisites to using braille andtactile graphics at school.Orientation and mobility instructors (O&Ms) also play asignificant role in teaching and reinforcing sensory skills.For example, O&Ms might teach a student who is blind toidentify where he or 213 she is by listening for environmentalsounds and noticing surface changes.O&Ms might teach visual and auditory scanning for cars,visually following a shoreline, and when to rely on othersensory information instead of unreliable vision. Thesesensory efficiency skills will continue to be useful as thestudent moves to unfamiliar postsecondary, community,and work environments.As shown here, teaching students how to efficiently usetheir remaining senses gives them greater access to theenvironment as well as increased independence andability to function.

TVIs

and O&Ms must receive training in how to assess and support the development of sensory skills. They need to understand which sensory cues are more reliable than others and help students learn to use these kinds of cues. For example, some sounds, such as a bell tower's hourly chime, might be consistent whereas the sounds of the outdoor air conditioning unit or water fountain cycle on outdoor

air conditioning unit or water fountain cycle on and off. TVIs also need to be aware of potential issues in the area of sensory skills and how to accommodate for them, such as if a student is reluctant to touch different textures or if a student has a hearing loss. Throughout the day, TVIs, O&Ms, and others should reinforce these sensory skills. This can be achieved by describing different textures for the student as he or she feels them, or by pointing out distinctive visual features like the black tape on each step in the stairwell.

The visually impaired person enjoys the experience in independent travel when he has a good and efficient training in use of the remaining senses. The loss of sight compensated by the sense of touch and hearing. Sensory stimuli enable a visually impaired person to determine his position or direction. Such sensory stimuli are classified as 'clues'. Hearing plays a dominant role in mobility.

Sharpening of hearing means much in the perception of the world as developed by the visually impaired student.

The important areas required for sensory training may be branched off as follows: 3.6.1

Importances and Procedures for Training Auditory

Sense of auditory is essential as we rely on auditory information of the world consciously or unconsciously. The visually impaired student has to depend on this sensory training to a great extent. It overcomes the difficulties of the student suffering from lack of visual perception.

Hearing plays a very important part in the orientation process. To gain maximum advantage, the person must use it in a number of ways: Sound Discrimination: refers to selecting those sounds which are useful for orientation. For example, in a background of a variety of noises in a farm, he may want to separate noise of a bullock cart to get an indication of pavement direction.

214 Sound Localization: refers to locating the sound in terms of its direction, distance, source quality, variety, angle and whether the sound is moving or not. Once the position of the sound is established, he may decide to move towards or away from it. For example, on locating a sound of an engine of a tractor, he may move away from it for the reasons of safety; or move towards it for approaching the pavement. The sound discrimination and sound localization help the visually impaired in the following ways: •••• Identify objects from their sound •••• Relate the sounds to their sources •••• Discriminate between simultaneous sounds •••• Establish direction and source, whether moving or not, of the sound •••• Localize sounds for understanding spatial concepts •••• Get an understanding of spaces, places, terrains by sound discrimination. Mapping of Sound: Whenever sound is perceived in the hearing system, mind of an individual tends to create a map in the mind depending upon direction, distance, angle, quality, variety and pitch of the sound. Individual's mind tends to recognize the source and location of the source depending upon these factors and relating the same to past experience as regard nature of sound. A visually impaired person also experiences the same process. She requires inputs terms of recognition of these sounds and relating the same to the source. A visually impaired should: •••• be encouraged to retrieve maps of sound generator in brain; •••• relate quality of sound with the source; •••• locates objects using this process. •••• experience and remember variety of sounds; Echo Location: refers to detecting obstacles through the noises which are generated by an individual and reflected back from the obstacles. It has been established that most congenitally visually impaired people are able to detect obstacles through echo location whereas adventitiously visually impaired people can be trained to do so. Limitations •••• echo location ability deteriorates with age; and

215 •••• echo location is difficult: in noisy conditions; when there is strong wind; and when the obstacle is very thin. It is thus essential that every visually impaired person should be imparted adequate and appropriate training in the proper use of the sense of hearing. It is desirable to use an auditory map for orientation of the environment. 3.6.2 Importances and Procedures for Training Tactile

Exploration of an object is worth a thousand words used in explanation. Objects perceived through touch, determine the definiteness of the objects and help the individual to form neat conception of them. More than mobility, the sense of touch has a lot to do with reading of the

visually impaired

student. It has its limitations as large objects lie beyond tactile exploration. 'Wholeness' can be perceived by the child only when the object is within the reach of the non-seeing child's hands.

A visually impaired person can gain a great deal of information by his sense of tactile. Touch is essential for concept clarity and determination of the nature of the object. He can use his tactile sense to explore the environment in the following ways: Hands can be used to: •••• understand spatial quality, surface texture, resilience, temperature, pliability and weight; •••• establish the position and then identify objects; •••• trail along any object for maintaining contact for mobility; •••• avail information about the layout of the environment through tactile maps, models, embossed diagrams and relief maps; and •••• understand the diversity of various objects. Feet can be used to: •••• understand the position of various landmarks on the pathways; •••• understand the relative position of buildings and the direction and lengths of connecting roads; •••• feel changes in surface texture, slope etc.; and •••• understand terrain and geographical conditions.

216 Touch may pose a limitation as large objects and the environment in general are invariably beyond tactile exploration. 3.6.3 Importances and Procedures for Training Olfactory

A good nose voluntarily offers the information of the objects which can be smelt. These are sensible clues for a traveller. During his travel, the smell of a gutter, the smell of smoking in a chemical industry, smell of flowers in a garden or smell of a kitchen are sources of information for him to locate where he is.

Development of this skill speaks well of the chemistry laboratory of the child's school experience. This also helps in the day-to-day life of the individual. If the student has an 'educated nose', his surroundings can transmit enormous information to him. ••••

Smell is useful for orientation, both in the house and the outside, in the following ways: •••• Particular shops, factories or establishments can be identified by odour. •••• Smell from kitchen, store or dining room can be useful as a cue for direction. •••• Through smell, one can establish presence of particular animals in the vicinity. •••• Typical odour from sewers or open drains in the rural areas can be used as landmarks. •••• Sense of smell is useful for understanding one's relative position in an agricultural or a dairy farm or a garden. •••• To relate or associate different items from their smell. Limitations •••• Sense of smells may change with time and with change in circumstances. •••• Difficult to differentiate smells in crowded places. •••• The same smell may be coming from different directions and locations. •••• Difficult to use this sense in isolation, thus to be used in combination with other senses. 3.6.4 Importances and Procedures for Training Gustatory It has limited utility for sensory training in orientation and mobility

as it does not provide any information about the relative environment or unless the sense is provoked, sensing is not spontaneous. This

sense, however, needs to be nurtured for its utility. It helps a

217 visually impaired person to associate names of the particular substances with their particular taste: •••• sweet with sugar, candy, sweets •••• sour with citrus fruits, juices •••• bitter with medicines, herbs, plants •••• hot with tea, coffee, milk •••• cold with ice-cream, ice, cold water etc. The sense of taste is particularly useful for identifying the ingredients of food items, drinks, and dietary substances and like items. 3.6.5 Importances and Procedures for Training Kinaesthetic Senses

The feeling of the body in responding to external stimuli, otherwise the kinaesthetic sense enables the child to get certain information like cold, heat, breeze and elevation of surface. Mobility is guided by his

kinaesthetic sense. Changes of temperature on the face or body can be used to provide orientation information. For example, it is possible to recognize position of the sun by the part of the face which feels hot. The relative position can be understood by a change from the shade to the sun. The response of the body to external stimuli, termed as kinaesthetic sense enables a person to avail environmental information like heat, cold, rain and breeze etc. The receptors in the joints, muscles and tendons give information to the brain about the physical position of the individual in the environment. This mode of information is termed as the kinaesthetic sense. Through this information, a visually impaired person comes to know the type of ground or surface i.e. grass, road, mud he is walking. It is possible to remember and repeat particular body movements. Taking meals involves a number of sequential body activities which can be remembered and repeated when required. With practice, particular muscular movements can be produced automatically in a similar situation. It is possible to replicate the extensive body movements involved in walking from one place to another. Getting into a bus, going up the stairs or opening the door generally involves particular muscular movement which can be repeated time and again in a similar manner.

3.6.6 Importances and Procedures for Training Residual Vision

Assessment of the students 'residual vision' is the first step in teaching how, when and under what conditions such vision can be used effectively. The ability and visual

218 functioning of people can be assessed through series of graded visual experiences. It is better and easier to move smoothly through familiar environment to the child. Vision develops in rational sequence. The activities are hierarchical and logical rather than random. The child, who tries to see, first attends to the light source. Often the child is developing the skill of residual efficiency through various stimulating activity and colourful objects. Sensory input is to compensate for the lack of sensory which they are receiving visually.

The suggestions are how to help the student fill their sensory needs or various opportunities which are possible at home and school are listed below. They are to be practiced for a prolonged time to improve residual senses: Development of an interest in seeing: •••• Stimulate visual curiosity by exposing the child to various lighting conditions. •••• Encourage continually to maintain interest in seeing. Variety counts a lot here. •••• Encourage for seeing first, the inaccuracies may be mentioned later. Encourage discussions about what is seen. The child may be assisted in making associations between three dimensional object and two dimensional pictures, picture to picture. •••• Develop a vocabulary dealing with visual likeness and difference. Encourage attending: •••• Providing enough time for the child to observe the objects. •••• Using coloured lights in positions of gaze may help the child to fix his line of vision. •••• High interest objects for identification. Objects like balls or toys can be used for this purpose. Tracking following an object: •••• The teacher can draw diagrams or letters and ask the child to move his finger along drawn pathways. •••• The child may be asked to follow a light source. •••• As crayon pencils are used by children. The child of low vision too can follow the pencil. Recognition of objects: •••• Discrimination three-dimensional objects, blocks, sticks and stones.

219 •••• Teach graduation in size. Small medium and big should be graded by the child. •••• Two- dimensional presentations. •••• Teach names of colours. •••• Teach intensity concept. Mildness or thickness are some concepts to be developed in the child. •••• Colour intensity can be made complicated and the child should be asked while he has seen Visual memory games: •••• Flash card or object presentations and the child should be asked what he has seen. •••• Increase duration of memory. •••• Increase difficulty of stimulus. •••• Decrease time to exposure. •••• Increase number of stimuli. •••• Specify order or recall. •••• Call for categorizing. Visual integration: •••• Use complete range of forms taught for this purpose. •••• Have child make shapes from stubs, clay, card board, wood pieces. •••• Draw forms freehand. •••• Throwing or catching a ball. •••• Being related black abstract forms to familiar concrete objects in environment. •••• Reinforce vocabulary of difference. •••• Emphasize naming of objects. Visual closure: •••• The child must be asked to find the missing parts of concrete objects. •••• Present a series of diagrams in ascending or descending order with one diagram missing in between. Let the child complete it.

220 Form constancy object programme: •••• Concrete, familiar objects may be presented in various positions and the child must be exposed to those differences. •••• Two-dimensional pictures of the objects in various forms may be presented to the child for discrimination. Figure ground discriminations: •••• Pictures of different colours may be given on the same back ground and the child asked to discriminate. •••• The complexity of discrimination can slowly be increased. Eye hand: •••• Tracing lines, curves and other two-dimensional forms or shapes are useful activities. •••• Rolling balls, throwing, catching and bouncing are some activities for developing eye hand coordination of a child. •••• Weaving with plastic ropes and cardboard needles develop motor skills. Eye foot: •••• Placing a foot game on squares of paper or mats demand the eye foot coordination skill in the child. •••• Following a weaving line made by a rope is good for skill. The low vision condition demands more creativity in the teacher owing to individual differences in the extent of visual impairment, amount of residual vision and the temperament of the children. The teacher in his approach should bear in mind the following to make his efforts more fruitful: ••••

Visual skills instruction includes learning to use visual skills, such as tracking, scanning, and attending to visual stimuli. Visual efficiency refers to the extent to which an person makes the greatest use of the vision that is available to him or her. ••••

Attending, shifting gaze and visual pursuit skills will help prepare a student for learning as well as prepare them for safe and efficient travel. •••• Tracking and scanning skills are important for reading and writing activities as well as safe and efficient travel.

221 •••• Visual motor skills help coordinate eyes and feet as well as eyes and hands. This page lists possible activities to help develop visual motor skills including gross motor, fine motor, and eye-hand integration. •••• Visual discrimination is the ability to recognize details in visual images. •••• Activities practicing visual closure and figure ground can be more challenging for students with visual impairments. •••• Visual association and visual memory activities can be challenging for students with visual impairments. ••••

The development of tactual exploration and discrimination skills are necessary for future braille readers as well as for students who may not be able to learn formal braille, but can learn to discriminate objects by touch to help make sense of their world or to use for communication.

222 •••• All students need to develop strength and dexterity to complete everyday tasks. This is especially important for future braille learners in order to be able to use the braille writer and slate and stylus. It is important for students to manipulate materials and develop their fine motor skills. This page provides suggestions on ways to develop skilful hands. •••• Listening skills are important for everyone, but especially for students who are blind or visually impaired strategies in developing a student's auditory readiness, a skill needed to lay a foundation for listening skills. •••• Many students who have visual impairments will be print readers and will use print as their primary mode of communication. The teacher of student with visual impairments (TVI) will assess the student's functioning and determine what non-optical devices will assist a student in accessing print and instruct the student in the proper use and care of the devices.

223

It is a misunderstanding to suppose that the loss of sight leads to extraordinary abilities in the other senses. In fact, the student lack of confidence in the remaining senses when blindness is abrupt. Unless the senses are attuned to the environmental demands of information, the abilities remain in halting positions. They must be provided with the opportunities to experience the use of senses and the utility should be noticed. For a child who has acquired the necessary sensory skills, orientation to environment becomes easier and this leads him to a greater level of confidence in mobility. 3.7

Techniques of

Teaching Social Interaction Skills, Leisure and Recreation Skills and Self Determination 3.7.1 Techniques of

Teaching Social Interaction Skills

Social bonds between children who are blind or visually impaired and their caregivers can be affected when there is lack of eye contact, possible lack of smiling, and frequent passivity or constant tactual exploration in less than ideal locations.

Providing students with fading assistance in social circumstances is key. Talking with the student about who is involved, what they are doing and why can help the student understand the social context. Although it may be difficult to provide, students need honest and sensitive feedback about their behaviour and the impact it may have on social interactions. You can then talk with the student about how they can make judgments about how to change their behaviour. Students must learn to communicate effectively with different people. They must also learn to accept and respond appropriately to suggestions and corrections (ex. show respect for their teachers and others in leadership positions). The strategies identified here may help the student develop appropriate and positive social skills. Help a student learn appropriate social skills by encouraging the student to: •••• identify conventional gestures used in social contexts. •••• use nonverbal behaviors to indicate interest in speakers and to communicate more effectively. •••• respect personal space of others. •••• make contact according to cultural norms. •••• turn face to speaker and maintain social interaction. Explain that this behaviour shows you are interested in what the other person is saying. •••• discuss facial expressions (ex. smiling, frowning, etc.) as feelings that occur throughout the day. Help students understand that their facial expressions convey to others how they feel.

224 •••• use a tone of voice that is appropriate to the setting. •••• recognize behaviors that can cause social isolation. There are various responsibilities which must be followed in social interaction, which also known as interaction tips or behavioural skills. These are as follows:

Adult Interaction Tips Students need to learn respect adults and to interact and respond to them differently than they would to a peer. Help the student have positive interactions with adults by encouraging them to: •••• respond to an adult's attempt to interact. •••• initiate interactions with an adult. •••• address parents or other familiar adults by name. (But by all means do NOT play the guessing game! It is unfair for the student to "Guess who it is.") •••• comply with simple directions and limits from adults. •••• demonstrate the ability to differentiate between familiar adults and strangers. •••• identify situations in which an adult should not be obeyed. Sadly, we live in a world where not all people can be trusted and not all people have good intentions. The student needs to be taught that it is OK to not listen or comply with some requests. **Peer Interaction Tips** It is important for students to learn how to interact appropriately with their peers. The following are strategies to use in order to help the student develop positive peer interactions: •••• When the student enters a new area, make certain that the student understands what other students are doing. •••• Particularly with younger students, describe the student's present and the activities in which they are engaged. •••• Remind the students to take a moment and listen to groups at play before they jump in with an intrusive question or comment. •••• Be prepared to answer questions about blindness simply and naturally. The other students will probably ask questions about a student with impaired vision.

225 •••• Remind sighted students to express their feelings with words. Remind them that the student that is visually impaired may not see their smile, frown, or other facial expressions. •••• If the student is learning Braille, consider having the student demonstrate reading and/or writing in Braille to the other students. •••• Encourage the student with visual impairments to use the names of others when talking to them. •••• Don't be afraid to let students with visual impairments know that they are expected to answer their friend's question or respond to their comment. •••• Talk about the importance of turn taking. This applies to game play as well as in conversations. Discuss the importance of listening to discussions and waiting for an appropriate time to comment or ask a question. •••• Assist the student in developing the important skill of initiating, continuing, developing and concluding conversations. •••• Encourage the student to demonstrate affection in socially appropriate ways, considering the person, place, and situation. **Courteous Behaviour** Students who are blind or visually impaired may not be aware of conventional courteous behaviors as they may be unable to visually observe them. For this reason, students will need to pay extra attention to environmental cues in order to know how to act in various situations. Modeling and practicing the behaviors including greetings, farewells and introductions in comfortable, familiar settings, will help the student in use the skill in new environments. In order to help the student develop courteous social behaviors by encouraging them to: •••• respond to farewells and greetings. •••• apologize to others when appropriate. A student may need support from an adult to help them understand the impact of their actions and how it offended or hurt others. •••• use people's correct names and titles when addressing them. •••• introduce self to others and introduce people to each other. •••• give appropriate compliments and praise to others.

226 •••• use acceptable language with consideration for the person or people present, the setting, and the social situation. •••• differentiate socially acceptable and unacceptable behaviors in a variety of situations. The student will obtain information from others about appropriate behaviour in unfamiliar settings. •••• recognize sarcasm, and respond in an effective manner. •••• use appropriate manners (e.g., please, thank you). ••••

follow classroom and school routines and procedures. Social Interaction Examples ●●●● Initiates/reciprocates greetings ●●●● Shows toys/items to peer ●●●● Plays game with peer ●●●● Requests assistance from peer ●●●● Invites peer to join play ●●●● Expresses empathy ●●●● Follows changes in conversational topic ●●●● Responds to nonverbal cues of listener

3.7.2 Techniques of Teaching Leisure & Recreation Skills

Leisure describes an individual's perception that one is to choose and participate in meaningful recreation. Individuals with developmental disabilities typically have an abundance of free time but do not usually use their leisure in constructive ways. Even so, leisure instruction for individuals with significant disabilities historically has low priority, and is often not taught. This may be due to the perceived difficulty associated with establishing and integrating leisure activities for individuals with significant disabilities. All human beings have the right to engage in leisure activities, and services that are provided to individuals with disabilities should offer opportunities to engage in these activities. Increasing the focus on teaching leisure skills has the potential to open new doors for students with disabilities. When individuals with severe disabilities develop leisure skills, it may enhance social, cognitive, domestic, language, and motor skill development. Specifically, individuals who gain leisure skills increase their activity level and social interactions and decrease their self-stimulatory behaviors (e.g., body rocking, hand flapping), due to being appropriately engaged in age-appropriate leisure skills that can be enjoyed across the lifespan that enable adults to experience an enhanced quality of life by increasing competence and self-reliance leading to an increase in opportunities to access least restrictive environments. These skills contribute to living a more self-supporting lifestyle and to achieving greater independence in life. The more skills adults acquire, the more enhanced their quality of life becomes. However, most individuals with significant disabilities are unlikely to learn leisure skills without systematic instruction, and even those that may acquire the skills are not likely to generalize to other environments or self-initiate without systematic instruction. Several studies have demonstrated effective methods for teaching leisure skills to individuals with significant disabilities.

Recreation and leisure are terms often used interchangeably. Both relate to what people choose to do in their free, unobligated time that is not otherwise used for work, school, or other activities like appointments and chores. Leisure time is any free time that can be used to pursue personal interests. Recreation is an individual's preferred pleasurable and enjoyable activities in which they engage during leisure time. Recreational activities can be sedentary in nature, like knitting, chess, playing musical instruments, or social networking in person or on the computer. It can also be active and enhance physical fitness and well-being. Examples of active recreation include walking, skiing, dancing, bowling, hiking, rock climbing, boating, bicycling, weight lifting, and goal ball.

Children with visual impairments, blindness, or deaf-blindness need systematic and purposeful instruction beyond the general education curricula to gain the skills necessary to be independent, productive, educated members of society. Recreation and leisure are some of the instructional areas that need to be addressed. Knowledge of recreation and leisure provides critical supports to a wide range of student capacities in the areas of social interaction, orientation and mobility, independent living, and self-determination. Developing recreation and leisure skills can have far reaching positive effects on the lives of people with visual impairments. Research has shown that recreation is an important factor in Recreation and Leisure and the Expanded Core Curriculum Back to: ECC Subjects and Skills

quality of life for everyone, including people with disabilities. People who engage in recreational activities will likely benefit by having improved cardiovascular function, better ability to sleep, improved self-esteem, increased stamina, and decreased stress levels, all of which not only improve quality of life, but also have positive benefits for other activities. Beyond the health and wellness benefits of physical fitness touted in the media, when one's body is more accustomed to the different types

of physical movements inherent in recreation and fitness activities, that person generally has better flexibility, strength, and stamina. With improved physical fitness, independent living skills are easier to perform and less stressful on the body. In addition, recreation is a highly social phenomenon organized around friendships or family groups, and these social interactions buffer the effects of stress on health. With this in mind, recreational activity that increases physical activity and improves fitness should be encouraged.

One's environment can be a determinant to stress reduction. Natural environments can be pleasant, relaxing, and stress reducing for many people, but large urban cities also provides the same experience. Having too much free time and limited access to various recreation activities of one's liking can produce stress. So, for those individuals living out in the country who have access to transportation, the joy of partaking in cultural events in the city on a weekly or monthly basis provides the opportunity for a stress limited lifestyle. The same can be said for people living in the city who recreate in the country. Social integration of children and adults with learning disabilities into community recreation programs offers the chance to develop a positive self-image through successful experiences and satisfying relationships with peers. McGill (1984) reports that integrated play opportunities are stimulating and highly motivating experiences for disabled children, offering them opportunities to imitate and model the play behaviour of nondisabled peers. Social integration also enhances relationships between family members. We've all heard of the old adage, "The family that plays together stays together." This adage infers that leisure experiences promote family satisfaction and stability. Recreation activities provide opportunities for couples and families to interact and negotiate individual and collective interests. Worthier and Mancini (1991) state some benefits to the family: Leisure experiences promote opportunities for developing equity. Unlike many other environments within which people interact, leisure experiences promote opportunities for each individual to maximize her or his own interests and minimize competition. It is during leisure time when husbands and wives, and parents and children, are most apt to practice by negotiating family roles and reaching new definitions of consensus. When individual interests are promoted over maximum joint interest, family bonds are weakened. Shared leisure experiences encourage opportunities to negotiate and improve the historical comparisons upon which subsequent negotiations are based. Benefits of leisure in social integration are also noted in people without disabilities. The chance to learn from and to socialize with nondisabled peers has been cited as one benefit for individuals with disabilities participating in integrated and fully inclusive 229 programs. Research in the 1980's determined that positive attitudes of children not having disabilities toward peers having disabilities were cultivated or increased when involved with an integrated recreation activity (Schlemiel & Ray, 1988). Recreation service providers also learn from this experience. Due to the Americans with Disabilities Act of 1990, all private, public, and non-profit agencies delivering recreation services to the public must supply accommodations and modifications within their programs to persons with disabilities. These professionals may not have any knowledge of providing accommodations and/or modifications to participants with learning disabilities. The person with learning disabilities, upon disclosure, thus needs to educate the professional about what accommodations and/or program modifications should be arranged to enable full participation in recreation programs. This social interaction not only contributes awareness of this situation to another person but also demonstrates how important it is for individuals with disabilities to participate in a particular recreation activity like everyone else. Often, the public and even some professionals who are knowledgeable about learning disabilities forget that everyone has a life after school and after work. Do not let the word learning impede any thinking that problems associated with learning disabilities will only surface during school or work. A person may read during leisure time, and that does not always mean a novel. A person reads directions to complete a craft project, instructions to play a computer game, a description of a recipe, and even the gate number on an airplane boarding pass. Dyslexia does not cease when one is playing Scrabble(R). Auditory perceptual ability does not suddenly improve because a child receives lower amounts of verbal instruction on the baseball field than in the classroom. Dyscalculia does not go away when playing a card game. Learning disabilities can affect every area of one's life, including participation in recreation activities. First, the person may only wish to participate in activities that reveal his attributes. For example, an individual who excels naturally in physical activities (e.g., basketball, volleyball, golf, tennis, etc.) may feel more comfortable playing in physical activities than a game of Scattergories, which requires the ability to hold information in memory, process written text quickly, recall accurately, and spell precisely. Even when a person excels in physical recreation activities, unexpected obstacles can appear. A few of these obstacles are reading and interpreting written game plays or formations (e.g., basketball, football, gymnastics, marching band, water polo, hockey, etc.), keeping track of a score (e.g., golf), and outmanoeuvring your opponent through replanted shots (e.g., racquetball,

230 volleyball, tennis). To, shown is a compilation of illustrations that describes how specific types of learning disabilities affect performance in recreational activities: ●●●● Dyscalculia. This can cause one to produce a sum that is incorrect, resulting in losing a game or in misplacement of ranking in golf. This also can cause difficulty in playing games such as dominos? Scoring bowling or in any type of card game? Casino gambling? Calculating dining charges, etc. ●●●● Dyslexia. This inability to understand written language poses a problem when reading craft instructions, theater programs, movie subtitles, travel itineraries, tour guide brochures, and interpreting the directions in learning a new game. ●●●● Auditory Acuity Difficulty. This may be the problem if, when playing a game of basketball, a player continually does not respond to a coach's directions from the bench or does not respond to a teammate's verbal playmaking messages. ●●●● Auditory Vocal Association Problems. The characteristic is displayed when a person hears what was said, is subsequently able to acknowledge the auditory stimuli in a correct manner, and yet proceeds to perform an incorrect or inappropriate action. In football, upon hearing the signal for an interception, a defensive back stop, turns, and begins to tackle opposing players rather than block. ●●●● Auditory Memory Deficit. This could be the problem if a person finds difficulty remembering directions or instructions that have been previously explained (e.g. Just before game or during halftime when new instructions were stated). In volleyball, a player does not remember alterations to a defines play made by the team captain at halftime. ●●●● Auditory Sequencing Problem. Here a student experiences the inability to recall a series of auditory instructions. During tap dance instruction the student performs a shuffle step beginning with her left foot instead of her right foot and before an eight count circle to her left. ●●●● Catastrophic Response. This can occur anytime when Catastrophic Response. This can occur anytime when the individual is overloaded with too much visual and/or auditory stimuli and results in high frustration. A scenario could be that the person misread or did not double check the time to return to the bus from an outing. This resulted in the person and accompanying friend missing the bus to return to their hotel. They are standing at the wrong bus station surrounded by hundreds of tourists. His friend is yelling, people are everywhere, and the person
231 shuts down for approximately one minute. ●●●● Cognitive Disorganization. With cognitive disorganization, a person may often miss or forget steps in a sequence. During a Cub Scout weekly assignment, 10yearold Bob never brings all of the materials required completing a project, or he constantly confuses the steps taken to achieve merit awards. ●●●● Crossing the Midline and Directional Problems: These problems become quite apparent during aerobic exercise or dance class, roller or ice skating instruction, driving small motorized vehicles (e.g., scooter, go-cart racing, bumper cars, boats, etc.) and locating a room in a hotel. This individual is unable to smoothly mimic the movements of the aerobic or dance instructor and experiences difficulty mirroring responses. Controlling the steering wheel, judgement of turns on a course, and going in the correct direction may require many practice runs before exhibiting adequate skills. ●●●● Disinhibition: A person exhibiting this problem often finds complications with "fitting in" groups, especially team recreation activities. Constant laughing at a teammate when the ball is dropped, always retrieving a shot within someone else's playing zone (e.g., volleyball), and continually talking loudly when silence is expected (e.g., opponent is putting in golf) could lead to dismissal from the team, if the individual is unable to correct these types of behaviors, or could result in peers not inviting this person to accompany them in a recreation activity again. ●●●● Intersensory Problem: Trouble using two senses at once could interfere with designing a piece of pottery or hand painting a ceramic dish and holding a conversation with a talkative person who is sitting in the adjacent seat. ●●●● Dilemma: Individuals exhibiting this dilemma may not complete the task or may make numerous mistakes during the process due to engagement in conversation. ●●●● Short term Memory Problem: A person with a short term memory problem does not remember the sequence of a turn taken during a table game, forgets to place a bet before the next poker round, and may not remember what he betted during the current poker round. ●●●● Visual Acuity Problem: A player does not exhibit the ability to see clearly and differentiate objects in his visual field. In bowling, the bowler experiences problems in lining the bowling ball up with the range finders on the runway.

232 •••• Poor Visual Coordination and Pursuit: Here the task of following and tracking objects causes distress. A person has trouble positioning him to catch a Frisbee or misjudges the landing of a spin on a tennis shot. •••• Visual Figure Ground Differentiation Problem: With this type of problem the person never identified where the object was from the beginning? She has an inability to distinguish between objects in the foreground and background. In soccer, a player has difficulty seeing her teammates when conducting a "throw-in" to continue the play of game. •••• Visual Motor, Spatial Form Manipulation Problems: An individual finds complications in successfully moving in space and manipulating three-dimensional objects with this problem. Examples are placing jigsaw puzzle pieces in their correct location within a puzzle, manoeuvring one's bicycle through an obstacle course, and even parallel parking one's car. It is common for persons with learning disabilities to employ survival strategies when learning a new skill or interacting in a group situation. Examples of these strategies are as follows: 1. Learn from doing. 2. Observe what others do. 3. Develop a buddy system. 4. Awareness of instructors' expectations: It is common in organized athletic teams that one person's wrongdoings or mistakes can jeopardize the entire team? Youngsters and adolescents respond quickly to peer pressure

How Do Teachers of Students with Visual Impairments (TVIs) Approach Instruction? Recreation for children with visual impairments cannot be learned by passively observing others at play. Recreation must be intentionally and systematically taught with disability specific techniques and safety in mind. The foundation for recreation can be learned in physical education (PE) courses with accommodations and adaptations. Children with visual impairments benefit from learning the components of recreation and fitness in PE because many other components of the ECC are also covered to some extent during the course of the year. By participating with classroom peers, students with visual disabilities learn the foundational sport and fitness skills that enhance the lives of all children. They are also empowered to make the self-determined decisions necessary to have control over their free time and make lifelong health choices. TVIs approach instruction in this area by providing students with specific information about recreation and leisure activities. They also collaborate with PE teachers and other professionals to determine how activities can be adapted for these students to maximize their opportunities

233 for independent participation and learning. For example, a tee might be used in softball instead of having the ball tossed to the student, or a beeper ball might replace the standard ball. For activities like basketball, things such as tape can be placed on the ground to mark the boundaries of the court, and a beeper can be placed on the basketball hoop to help the student identify its location. These students can also be introduced to sports that have been specifically created for those who are blind and visually impaired, such as goal ball and beep baseball. TVIs also support recreation by describing the activities in which the student's peers are participating. They model those activities for the student and school staff who work directly with the student in other areas. The TVI might teach the student how to play games that classroom peers are playing or show the student how the activities can be adapted. For example, braille might be added to playing cards or friends might read game materials to the student. The TVI can also orient the child to the school playground or PE field and show the child how to use various play areas and equipment. During direct instruction, TVIs or orientation and mobility instructors (O&Ms) describe the recreational activities in which people around them are participating. In addition to verbal descriptions, tactile maps and diagrams can be used to teach layouts of various activities. Examples include a tactile map of a baseball or football field that may indicate the different player positions. Even if youths who are blind and visually impaired choose to not participate in every sport or recreation activity on their own time, they should learn what the rules are and how to play them. Knowing the rules of different games and keeping abreast of sports offers a student with visual impairments opportunities for social interactions with peers. Remembering that recreation, fitness, and leisure skills encompass more than physical activities, students with visual disabilities should be introduced to a variety of hobbies they may find interesting. Even if a student chooses to not participate in a hobby over the long term, the student will have a greater understanding of how people spend their free time and be able to participate in conversations about these activities. The overall goal of the TVI is to help the student identify recreation, and leisure activities that he or she enjoys and can pursue throughout life.

As with all people, regardless of ability or personal interests, recreation, fitness, and leisure skills are an important ECC area that supports the sense of both wellbeing and quality of life for students who are blind and visually impaired. Because these students have difficulty seeing how others spend their free time, TVIs and O&Ms systematically and purposefully help these children discover and learn about activities they may enjoy. Participating in recreation, fitness, and leisure helps youths with visual impairments develop social, career, and problem solving skills.

234 Engaging in this ECC area also increases self-esteem, self-determination, and overall health. Students who are challenged and achieve goals they thought might be impossible, or too difficult, develop confidence which positively impacts all areas of their lives. To that end, TVIs should be aware of how to adapt a variety of recreational activities for these children and work with PE instructors to ensure that they are included in their PE classes. We do not want youths with visual impairments to be idle bystanders in life? They should be engaged in recreation and leisure activities alongside their peers to ensure they learn the skills necessary to make purposeful and self-determined life choices.

The student should be encouraged to: choose an object to play with or an activity when presented with options; play simple card, board and table games; identify various community activities and facilities; participate in clubs/activities; identify and choose appropriate leisure activities and hobbies; play age-appropriate games enjoyed by peers; and cooperate in team activities.

Before suggesting the leisure and recreational skills must be follows underneath factors: 1. Generalization data demonstrated these two participants successfully maintained the skill over time, as well as in other environments. 2. The selection of games is very important. The games should be aimed at the appropriate developmental level of child, and adaptations should be made 3. So they are suitable for a particular child, if necessary. Most importantly, the games should be playable with nondisabled peers. 4. In addition to using games that need no modifications, there are numerous adaptations that can be made to games that will allow blind and visually 5. Impaired children access to a wider range of recreation/leisure activities. 6. Some of these adaptations are: Divide sections of game boards with glue, or various textures. Add braille labels to sections of game boards. Use velcro in sections of game boards and on bottoms of playing pieces. Braille the instructions and the game cards Tape record game instructions. Braille regular playing cards or game cards such as Uno. Use textures or glue to mark differences in game pieces. Add brightly colored stickers to game pieces and game sections. Mark dice with braille labels or glue dots. Make a Tic-Tac-Toe board with a cake pan and magnet strips. Divide checkerboard with glue and mark red playing pieces with texture. Play Tic-Tac-Toe with pegs and pegboard. Use a large box lid to define playing space. And Keep score with peg boards, paper clips clipped to index cards or tokens dropped into a contain

Play

235 Play is the foundation for learning about the world. Through play, children learn to make comparisons between materials and develop preferences. Children learn many skills through play and also begin to develop social skills. Play is an important part of the Early Childhood curriculum, but children may need to continue to develop their play skills even as they elementary school. Playground The playground should be adapted for the student with visual impairments. It is important for a student to be oriented to a playground when it is quiet and when other students are not on the playground. In addition to learning where the equipment is located, students should have the opportunity to tactually explore the equipment to learn how it moves. Student should also be instructed to visually scan the playground and/or use auditory cues prior to moving from one area to another. Creativeness All children will naturally gravitate toward a preferred activity.

Of

course, students should be permitted to develop in their area of interest, but it is important to expose children to a wide variety of leisure activities to ensure the students are aware of a variety of leisure activities available. Students who are blind or visually impaired do not have the same opportunity to visually observe a variety of activities available. Factors such as cost and material adaptations will play a factor in what activities are accessible Bowling Students can learn basic bowling skills by playing with home-made or purchased bowling sets that can be used at home and school. A sound source can be placed behind the pins in order to provide an auditory target for the students. Many bowling alleys will provide bumpers, or portable bowling rails, upon request.

Word, Card & Board Games Playing games is a lifelong leisure time activity that fosters social interactions. In order to be accessible to a student with a visual impairment, they may need to be adapted. Although someone knowledgeable in braille can adapt card and board games, there are commercially available games that have been adapted with braille as well as large print. Large print cards can be purchased or made for students with low vision. Bicycling The foundation for bicycling can begin when a child is young. Providing opportunities

236 for students to play on riding toys is a good introduction. Older students can build endurance and experience physical activity by using a stationary bike. Students with low vision may be able to learn to ride a bike, but depending on their level of available vision, may need to ride alongside a sighted adult or peer who can warn the student of any dangers. Students who are blind may be able to experience biking using a tandem bicycle. Physical Games & Sports Simple games can be adapted easily, but it may be more challenging to adapt team sports. Although games can be adapted, students will need to acquire the motor skills necessary to fully participate in the games. Skills needed to play in games may need to be taught in isolation. It is important to be aware of the students are more at risk for retinal detachment. Also, some eye conditions can be aggravated by vigorous physical activity.

Practice different ways to cross the gym/playground: walking, tiptoe walking, galloping, skipping, hopping, and

running with a partner, jumping. Make it a game of walking up and down stairs in a "Teacher May I" game. Practice jumping up and down with jump rope or Chinese jump rope games. Practice keeping balance while walking along curbs or balance beam. Play games that incorporate throwing and catching balls. Encourage student to slide, climb on play structures, crawl through tunnels, and play on swings. Encourage students to create their own obstacle courses and challenge their friends. Students are able to use recess and gym time to gain an understanding of their bodies in space; improve their physical skills; develop language and concept development; and practice group cooperation. Many of the team games and athletics are excellent and appropriate for students with visual impairments.

In addition, however, these students need to develop activities in recreation that they can enjoy throughout their adult lives. Most often sighted persons select their recreation activity repertoire by visually observing activities and choosing those in which they wish to participate.

Perhaps nothing reveals so much about individuals as how they choose to play how they invest their time and energy for leisure time. Leisure is that time free from demands of school, work, or required activities of daily living. Everyone needs regular recreation that develops skills, promotes good health, relieves stress, facilitates social interactions, and provides a general joy for living. For recreation, choose activities at which can be successful. Good readers read. Athletes seek sports' activities. Musicians lose themselves in music. Visual artists paint or draw. Craftspeople create. Social individuals engage in group activities. Observers appreciate the efforts of others whether a basketball game, painting, fine

237 meal, or concert. Children, adolescents, and adults with learning disabilities may find themselves with limited opportunities to fully enjoy leisure time. A lack of perceptual, motor, memory, linguistic, or organizational skills may cause them as much difficulty for leisure as they have at school or work. Fear of failure may limit their reaching out to access recreational activities. Just as we teach children with dyslexia to read, those with math disabilities to understand math, those with linguistic problems to better comprehend and use language, we must teach skills and provide practice so individuals with learning disabilities can achieve some recreational proficiencies. When skills are not as well developed as necessary and compensations are not made, agencies, institutions, instructors, and coaches can be helped to make necessary accommodations. Satisfying leisure time for persons with learning and other disabilities is as important as accomplishments at home, school, and work. Simply because they can derive many benefits from recreation participation. One benefit is learning from the experience. When the recreation activity experience has captivated the participant, this individual brings particular personality styles of learning, motivation, and expectations about the experience to the setting. The person faced with a specific environment, interpreted by the person or not, promotes one or more learning experiences. These learning experiences can be motor learning, understanding game directions, or performing a skill, all to meet the demands of that setting. These experiences may come from involvement in a structured recreation program and may be exhibited as part of the information outcomes of participation. Researchers in the field of learning and educational psychology have discovered a variety of learning outcomes. The following outcomes can be present because of participation in recreation activities: behaviour change and skill learning, direct visual memory, information (factual) learning, concept learning, schemata learning, metacognition learning and attitude, and value. The physiological benefits of recreation participation were derived from studies where people engage in physical activity of some kind (e.g., exercise, cycling, swimming, walking, jogging, running, hiking, weight lifting, etc.). Specific results from involvement in a physical recreation activity are an increased lung capacity, reduced resting heart rates and lower blood pressure levels. Other benefits consist of decreased body fat mass, increased lean body mass, increased muscle strength, and improved structure and function of connective tissues (ligaments, tendons, cartilage) and joints. Weight bearing and strength building activities help sustain bone mass and reduce the incidence of trauma induced fractures. Moderate physical recreation activities are known to reduce the symptoms of mild or moderate depression and anxiety through improved self-image, social skills, and mental health. Noted psychological benefits of recreation activity are as follows: perceived sense of

238 freedom, independence, and autonomy, enhanced self-competence through improved sense of Self-worth, Self-reliance, and self-confidence, better ability to socialize with others, including greater tolerance and understanding, enriched capabilities for team membership, heightened creative ability, improved expressions of and reflection on personal spiritual ideals, greater adaptability and resiliency, better sense of humour, enhanced perceived quality of life, more balanced competitiveness and a more positive outlook on life. Involvement in recreation activities releases stress and tension from the perils of society. Braum (1991) recalls the findings of researchers that state, "Relaxation tends to alleviate many of the symptoms of stress. Activities that fill leisure time, performed within a group, strengthen social support ties known to negate stress". The idea of choice in leisure presents opportunities where one can recreate.

3.7.3 Techniques of Teaching Self-Determination

Self-determination and control over one's own life is critical for all individuals, including individuals with developmental disabilities (Kennedy, 1996). Self-determination provides the conceptual foundation for policy, vision, and social systems in the field of developmental disabilities. As the field has evolved from early assumptions about "handicap" and "disability" the central role of the individual has been captured by the construct of "self-determination." A need exists to link the vision with both existing empirical evidence, and overt description of the practices that will help us better realize a society in which self-determination represents the lifestyle of all citizens. Promoting self-determination has become best practice in the education of students with intellectual and developmental disabilities. The purpose of this practice guide is to review and summarize existing practices that enhance self-determination and the empirical support associated with those practices. Self-determination offers a broad vision with personal implications. It is a construct with multiple facets and as such there will be no single practice or package of practices for achieving self-determination that applies to all people or all contexts. A full discussion of the definitional and theoretical frameworks that supports the work of the Gateway to Self-Determination project can be found in Wehmeyer et al. (2010). In summary, approach self-determination within a social-ecological approach in which self-determination is a psychological construct that refers to self- (vs. other-) caused action-to people acting volitionally, based on their own will. Volition refers to the capability of conscious choice, decision, and intention. People who are self-determined, as such, are causal agents in their lives; they cause or make things to happen in their lives. They do that through self-caused action (causal agency) that has a clearly specified goal or purpose or through actions of others taken on one's own behalf, referred to as proxy agency. Core assumptions associated with this approach are:

- All people can engage in self-determination
- Disability or severity of disability does not preclude opportunities for people to become self-determined individuals
- Self-determination is a multidimensional construct
- Promoting self-determination for any person will require the unique combination or clustering of practices that meet the needs of that person.

Delivering the promise of self-determination will seldom involve one practice, and will typically require individualized application of multiple practices.

- Self-determination is affected by not only by the skills and beliefs of the individual but by the social and societal context in which they live. Within our social-ecological approach, activities to promote self-determination (e.g., interventions) might focus on building a person's capacity to perform actions leading to greater self-determination (problem solving, decision, making, goal setting, self-advocacy, etc.), focus on modifying the context or the environment in some way to better enable someone to make things happen in their own lives, or to provide supports (e.g., technology) that enhance self-determination. For purposes of understanding these activities, in addition to activities derived from the theoretical models described in Wehmeyer et al. (2010), we turn to The Developmental Disabilities Act of 2000, which defined "self-determination activities" as "activities that result in individuals with developmental disabilities, with appropriate assistance, having: (a) the ability and opportunity to communicate and make personal decisions; (b) the ability and opportunity to communicate choices and exercise control over the type and intensity of services, supports, and other assistance the individual receives; (c) the authority to control resources to obtain needed services, supports and other assistance; (d) opportunities to participate in, and contribute to, their communities; and (e) support, including financial support, to advocate for themselves and others, to develop leadership skills, through training in self-advocacy, to participate in coalitions, to educate policymakers, and to play a role in the development of public policies that affect individuals with developmental disabilities."

240 What is Self-Determination? Why is it Important? Self-determination is broadly defined as having abilities and opportunities to steer one's life in a direction that contributes to a personally satisfying life.¹ Equipping students with the skills, attitudes, and opportunities to play an active and prominent role in their learning and planning for the future is now considered a best practice in the field of special education. Research suggests students with disabilities who are self-determined may: ●●●● Be more academically successful and engaged in schoolwork ●●●● Contribute actively to their educational and transition planning ●●●● Experience more postsecondary involvement ●●●● Report higher quality of life and more positive experiences in early adulthood ❖❖❖❖

❖❖❖❖ What are Choice-Making Skills? Why are they Important? Choice making involves giving students opportunities to choose instructional activities, partners, and schedules. In each instance, students should be allowed to choose among several options based on their preferences. Giving students the opportunity to make choices enables them to develop skills of demonstrating control and responsibility in their environment. Incorporating choice making into the daily activities of students with intellectual and developmental disabilities has been associated with a higher level of task engagement and a lower level of problem behaviour. Example Strategies for Educators Provide two or three learning activity options and allow students to make a choice

241 based on their preferences. As students become more proficient with making choices, they can be given more options to choose from. For example, in a physical education class, a student could select from a variety of activities (e.g., kickball, jumping rope, or running) for a 30-minute period of free exercise time. Allow students to choose how they will demonstrate mastery of a specific curriculum topic (such as cultural awareness). For example, a list of choices could include a written report, poster presentation, slideshow, collage, native meal, dance, or customs overview. When appropriate, give students choices about how they will carry out particular learning tasks, such as where they complete their afternoon assignment or with whom the choice-making process to help students better understand how to make choices on their own. For example, a teacher could model how she chooses what to eat for lunch given select cafeteria options by thinking out loud and then have students make their own choice. For students who have difficulty making choices independently, give advance notice of the options they will need to choose from, visuals of the available options, or more information about each option ❖❖❖❖

❖❖❖❖ WHAT ARE DECISION-MAKING SKILLS? WHY ARE THEY IMPORTANT? Decision making involves analysing a situation to determine possible outcomes, choosing the best scenario for yourself at that particular time, and following through with your decision. Students who are more self-determined will consider how their decisions affect themselves and others. Decision making is especially important at the secondary level, when students are considering future career and postsecondary pathways they will take in adulthood. Decision making involves consideration of all alternatives, positive and negative consequences, and what is the best for oneself. This collection of skills is important for everyday life situations-both in and out of school-where students will be faced with the need to make wise decisions.¹² Example Strategies for Educators Incorporate opportunities to make decisions based on the full list of options, the costs and benefits of each option, and analysing any bias present in picking various options.¹³ For example, talk with students as they decide what they want to do after high school. Options might include finding a job, going to college, and/or volunteering. Encourage students to adopt the process of stopping what they are doing, thinking about the decision options they have, and acting upon the most appropriate option.¹⁴ Teachers or counsellors could allow students to practice using this process in "real world" situations, such as deciding whether or not to engage in an argument with someone. Before acting on their emotions, students should decide whether it would be most appropriate to defend their

242 perspective or walk away from the situation. Teach students how one decision can have multiple impacts, such as deciding whether or not they should volunteer with a school club or community organization. While the decision may allow them to gain valuable skills and experiences, it may result in them having less time for friends. Teach "group- think" decision activities based on role-plays, stories, and videos when students are first developing this skill. These activities allow students to practice decision making in a safe environment. ❖❖❖❖ WHAT ARE PROBLEM-SOLVING SKILLS? WHY ARE THEY IMPORTANT? Problem solving refers to the capacity to identify a problem, generate possible solutions, evaluate the effect of each alternative, and ultimately choose the best option.¹⁵ Often, students use problem-solving skills during activities, tasks, or situations that do not have an obvious or pre-determined solution.¹⁶ Problem-solving skills are especially useful as students encounter situations requiring independence and competence in school and community activities. Further, these skills can assist students in community-based and work settings, where they often are expected to engage in tasks independently. Problem solving can also help students navigate social difficulties with peers, teachers, family members, or other members of the community. Example Strategies for Educators Help students develop the ability to find an appropriate solution when faced with a challenge. For example, if a student forgets her homework, cheating or lying would be inappropriate solutions and could potentially result in negative consequences. However, using free time to complete the assignment again would be a better solution with more positive outcomes. Have students reflect on the way they solved a challenging situation and make adjustments for future situations so they may enhance their problem-solving skills. For example, after participating in a group activity, talk to the students about their role in the exercise and whether they worked well with others. Present and explain a limited number of solutions for younger students or students who struggle with solving problems effectively. For example, if a student leaves a necessary book at school, the student's parent might present possible solutions, including asking to borrow the book from a friend, calling the school to retrieve the book, or checking the local library. Teach students conflict resolution strategies for times when issues arise with their peers, co-workers, family members, or teachers. For example, if a student becomes frustrated with another teacher in the building, brainstorm ways the student could address the issue with that teacher in appropriate, respectful, and mutually beneficial ways.

243 ❖❖❖❖ WHAT ARE GOAL SETTING AND ATTAINMENT SKILLS? WHY ARE THEY IMPORTANT? Goal setting and attainment skills require students to identify something they wish to work toward and develop a plan to reach that particular objective. When learning how to set and attain goals, students should be faced with challenging yet feasible objectives that are aligned to their likes and dislikes. Learning how to set and attain goals may enable students to better understand and work toward what is most important to them. The attainment of these goals may be encouraging to students as they seek direction and independence in school and life endeavours. Example Strategies for Educators Work with students to develop plans that include steps to reach a goal and any necessary resources. It is important to support students in considering the process of reaching the goal and not narrowly focusing on only the end result. Help students set manageable and realistic goals that can be met in a short time period (e.g., a single class period, a day at school, or over the weekend). For example, a student might set a goal of reading a certain amount of pages in a 30-minute block of silent, sustained reading. The student can learn to track progress and adjust her goal over time. Display students' academic and personal goals publicly and positively, and have frequent discussions about the progress being made to reach the goals. Encourage students to set goals they might find less interesting or preferable (e.g., academic or organizational goals) in order to encourage the development of their work ethic. ❖❖❖❖ WHAT ARE SELF-ADVOCACY AND LEADERSHIP SKILLS? WHY ARE THEY IMPORTANT? Self-advocacy and leadership skills involve having the ability and confidence to stand up for oneself, as well as having the knowledge of what to advocate for in achieving one's goals. The ability to lead requires students to be assertive and negotiable, communicate effectively, and utilize interpersonal skills. These skills are important as students seek to promote their interests and goals in post-school employment and community involvement. As students communicate with peers and community members, their self-advocacy and leadership skills may assist them in being understood and supported by others. Further, learning to work in teams, either as the leader or a cooperative member, may be beneficial in school or work settings. Example Strategies for Educators Design role-play situations where students practice advocating for themselves in a safe

244 environment. These situations should reflect encounters students will likely face in everyday community and employment settings. Examples may include ordering a meal at a restaurant, volunteering for a community event, sending an email message, or interacting with co-workers. Encourage students to advocate for their own preferences, desires, or opinions when appropriate. For example, if a student has a different opinion than the rest of the class, encourage her to speak her mind. It may also be beneficial for students to practice these skills in advance of participating in IEP and transition meetings. Model differences between acting assertively and acting aggressively so students gain an understanding of socially appropriate interactions. Teaching students interpersonal communication skills may allow them to successfully voice their opinion without offending others. Pair students with an older student or adult "mentor" who has similar interests, strengths, or limitations. This older person may be able to offer advice and anecdotes from previous experience where they exercised self-advocacy and leadership. ❖❖❖❖

WHAT ARE SELF-MANAGEMENT AND SELF-REGULATION SKILLS? WHY ARE THEY IMPORTANT? Self-management and self-regulation skills involve students monitoring and assessing their own behaviour, time management, and learning. These skills build upon students' competencies in the development of choice making, decision making, problem solving, and goal setting. As students' progress through school and prepare for life in the community, they should turn less to teachers and others first and instead become more self-directed. By learning to manage and regulate their daily activities, students may achieve more positive and productive outcomes, such as academic success, job retention, and employer satisfaction. Example Strategies for Educators Help students learn how to reflect on their behaviors by having them create a journal of their daily academic, behavioural, and social goals. This allows students to explicitly set their own daily and weekly goals. Students should be encouraged to effectively manage and regulate their own behaviour to meet these goals. Offer supportive feedback when students are correctly self-managing their learning or social behaviors. When students are struggling to manage themselves, offer limited support until they are able to independently correct their actions. For example, if a student is continuously talking to her neighbour during an assignment, offer reminders of the importance of staying on-task and not preventing others from learning. Provide instruction to students on how they should deal with various behaviors and emotions, such as anger or sadness. Develop a procedure with individual students so they can appropriately calm down when upsetting

245 situations occur without interrupting instruction or distracting others. Support students in directing their own academic progress and instruction by reflecting on their learning preferences, academic strengths and areas for growth, and academic goals. ❖❖❖❖

WHAT ARE SELF-AWARENESS AND SELF-KNOWLEDGE SKILLS? WHY ARE THEY IMPORTANT? Students who possess self-awareness and self-knowledge recognize their own strengths, limitations, and abilities. Moreover, they can apply this understanding to improve on their previous experiences and accomplishments. Students should gain increasing awareness about how they best learn, communicate, and appropriately deal with their emotions. When faced with difficult situations in school, professional, or family settings, they may utilize these skills to focus on their strengths and achieve success. Example Strategies for Educators Emphasize to students that everyone has their own abilities and unique personalities. To help students understand how people can be different, design a class activity where students role-play as if they were someone else to accept various perspectives, prejudices, and stereotypes often held by others. Have students reflect on their strengths and limitations and write these down in a journal. Then talk individually with students to brainstorm ways to maximize their strengths and minimize their limitations in school, interactions with peers, future employment settings, and community activities. Provide case studies on situations students may encounter in and out of school. For example, analyse a narrative in which a student noticed others becoming frustrated with her. Work together to determine what actions on the student's part may have caused the other students' reaction. Have students reflect and write down how they would handle this situation and how this hypothetical encounter would make them feel.

6.6 Lets Sum Up Independent living skills make every person confident about own personality. Not only efficient people but also impaired person gets benefits from these. It helps for doing day to day's works smoothly without any hesitation. After got proper training every single of work disable child can able to do independently. Orientation and mobility skill make the child for capable of travelling anywhere at any time without any other's help. On the other hand daily living skill makes an impaired child self concern about their everyday living hood. Whereas sensory training prepare the child for using their remaining senses almost fully. And last of all every type of living skill help the child to overcome their

246 impairment and change their behaviour which match with their surroundings or can able for making easy adaptive nature as society want. Most of all it must be said that independent living skill help the impaired person being an individual socialized man.

6.7 Check Your Progress 1. What is independent living skill? 2. Write the difference between orientation skill and mobility skill? 3. What is sensory efficiency? 4. How you develop social interaction skill in visual impaired child? 5. Write down any one daily living skill's task analysis process.

248 Unit - 4 □ Curricular Adaptation 4.1 Introduction 4.2 Objectives 4.3 Concept of Curricular Adaptation 4.3.1 Need and Importance of Curricular Adaptation 4.3.2 Scope of Curricular Adaptation 4.4 Process of Curricular Adaptation 4.5 Reasonable accommodation 4.6 Strategies of Curricular Adaptation for Different Subjects 4.7 Principles of Adaptation 4.8 Lets Sum up 4.9 Check Your Progress 1.10 Reference 4.1 Introduction The classroom offers a dynamic, productive space where ideas, values, information, knowledge are shared and conveyed. Organization of the class and interactions amongst its fundamental components i.e., the students, teacher and curriculum-transactions, create potential for the group to move from a state of not knowing to one of knowing. In light of the introduction of several educational innovations and initiatives, the attention drawn and the urgency to make classrooms better call for revisiting and revising practices. Creating an inclusive culture in classroom will involve attending to the curriculum. Curriculum includes the components of a course of study. These consist of the syllabus, textbooks and needed teaching learning materials, teaching strategies/processes and assessment and evaluation processes. In recent years, increasing focus on inclusion has brought significant attention from educators, policy-makers, researchers and economists, to schools and classrooms in India. Constitutional provisions, legal mandates such as the Right to Education (RTE)

249 Act, 2009, Persons with Disabilities (PWD) Act, 1995 and other measures have made improvements in India's education system. We can find that there is a changing nature of the student population and increased integration of students with special needs in mainstream education. It demands even greater flexibility in curriculum and creativity from teachers. The lack of specific curricular guidelines for students with special educational needs in post-primary schools, for students with mild general learning disabilities in special and mainstream schools and for students with severe and profound disabilities was identified as a significant shortcoming. Current research indicates that there is no simple answer to the provision of curriculum for special needs. In the present unit we will discuss the curriculum adaptations strategies needed to be carried out for children with visual impairment. We would also try to understand the role of teacher and other professionals of educational institution in curricular adaptation for catering specific needs of students with visual impairment. 4.2 Objectives: When you will complete

this unit, you will be able to:

- Explain the need and importance of curricular adaptation for students with visual impairment.
- Illustrate how curricular and lesson or unit adaptation could be carried out for students with visual impairment.
- Understand the role of teacher in curricular and lesson adaptation for catering needs of students with visual impairment.
- Demonstrate techniques of curricular adaptation for the students with visual impairment and related competencies.

4.3 Concept of Curricular Adaptation As discussed earlier that Right to Education Act, 2009 led to the changing composition of classrooms. Students with varying levels of abilities are now widely available in the classrooms. It also creates an obvious challenge for the education system, teachers and professionals to cater the wider range of specific educational needs. 'They cannot, and 250 should not, be taught in the same manner as with other children. The curriculum consists of all the learning experiences designed or encouraged to promote the educational aims and objectives of the educational programme of any institution. It sees curriculum development as a dynamic process, which is evolving rather than established. The curriculum assumes that institution or appropriate authority will adapt and interpret the curriculum where necessary to meet their own requirements. There is no fixed formula or procedure for adapting general education curriculum to meet each student's needs including children with disabilities. Each teacher, each student, each classroom has some unique features and requirements. Accordingly, adaptations are specific to each specific situation. Keep in mind also that curriculum does not always need to be modified. Some approach upholds the idea that one cannot create a modified curriculum for the specific cognitive development of groups of people, and that all that is needed is technical accessibility resources for these groups.

Another approach,

however, claimed that the development of the single curriculum, without any adaptations that take diversity into account, can reinforce the excluding practices, now under the form of abandonment and neglect of those students at "the back of the classroom", and lead to the dangerous labels of "learning difficulties". These colleagues argue that the fundamental thing is the creation of the "inclusive school", the one that is so flexible that it is open to receive everyone, and also the necessary curricular adaptations for everyone's needs to be met. They claim that the curriculum is unified, anyway, only that at the moment of implementing it, instead of a single strategy, adaptations are implemented. 4.3.1 Need and Importance of Curricular Adaptation National Curriculum Framework (NCF) 2005 underlines the significance of making curriculum "an inclusive and meaningful experience for children" stating "this requires a fundamental change in how we think of learners and the process of learning." Attending to curriculum to define the classroom culture and the approach to the teaching-learning processes is thus a significant aspect of teacher's work in fostering inclusivity in their work with students. It is important that the school should provide enabling experiences so that children with visual impairment experience success in learning and achievement up to their potential. This is only possible if the teachers respond to the specific needs of children in a classroom through curriculum adaptations. Without adaptations/ 251 modifications, some children in the classrooms would never be challenged to perform up to their potential, while others may not be able to ever experience success.

In order to meet the diversity, there is a need for adaptations of the regular curriculum, may be involving organizational modifications in the goals and contents, In the methodologies, in the didactical organization, in the temporality, and In the evaluation philosophy and strategies, making it thus possible to meet everyone's educational needs in the creation of knowledge.

Such adaptations need, necessarily, to involve the whole institution's team avoiding the transfer of responsibilities.

Curriculum adaptations require strategies for effective teaching in the classroom that takes into consideration the individual needs of all children including children with visual impairment. It has also been seen that adaptations if carried out effectively facilitate both academic and social participation in class activities and can be used across various settings to facilitate success. Adaptations can also help in creating partnerships where parents and teachers can work together to evaluate/ implement adaptations. 4.3.2 Scope of Curricular Adaptation As we know that curriculum is a comprehensive concept therefore, adaptation in curriculum also has several implications. We can also say that there is extended range or scope for implementing adaptation strategies from planning to content and classroom instruction to assessment. Broadly, adaptation could be understood in two categories. First is accessibility adaptation and second is pedagogical adaptation of the curriculum. Accessibility adaptation is about eliminating architectural barriers, whereas pedagogical adaptation is about changes in and methodological barriers in curricular area in children with disabilities.

252 Majorly of these types of adaptations are discussed in context of inclusion of students with special needs in regular classes.

On the accessibility dimension, it was stressed over accessibility and school permanence and do not necessarily assure knowledge acquisition and teaching quality directly. At different points it has been advocated that the students with disabilities are thrown into regular classroom without proper pedagogical preparation of the teachers or curricular adaptation. The worry highlights towards mere physical inclusion of the students with disabilities. How to teach the student with disabilities are together with the other students is the biggest "knot" and challenge of inclusive Education. Because, the point inclusion is no longer a philosophy, an ideology or a policy. Instead of that it becomes

a concrete action in real-life situations, involving individuals with specific difficulties and needs. 4.4

Process of Curricularisation In a classroom environment, quality education would depend upon a number of factors.

253 Crucial amongst these are understanding of special needs of learners, infrastructural facilities, modified environment that is warm, welcoming and inclusive, trained motivated teachers, flexible educational content, strategies for teaching and evaluation, sufficient teaching time, access of every child to teaching learning materials and continuous onsite support to the teacher by specialists if required. A curricular adaptation involves an activity or skill related with decision-making process. Attaining correct, proper and wider adaptation in curriculum is desirable. The following decision-making flowchart can be used to conceptualize the process of selecting and implementing curricular adaptations. It should be used as a tool for a team in determining the adaptation according to individual student's needs. 4.5 Reasonable Accommodation It is important to correlate adaptations with the classroom activities. In other words, we are not adapting for adaptations sake but, to meet the student's needs as identified. Therefore, accommodation is expected in all three areas i.e. teachers, students and learning materials: Teachers teaching content using diverse strategies: These include strategies like verbal, visual, kinesthetic, written, proceeding from simple to complex, concrete to abstract, step by step, scaffolding, group work, peer tutoring, using prior knowledge, brainstorming, dramatisation, giving extra time, giving alternative activities, drill activities, shortening assignments, organizing excursions/ trips, using large fonts, Braille or tacitly coded material, toys or blocks, real life experiences, real objects, children's literature, magazines etc. Students expressing learning in diverse ways: These include strategies like oral, written, tactual, gestures, drawing, acting, ICT, framing questions, paired reading, storytelling, song, rhymes, role play, discussions, debates, language games, flash cards, quizzes, graphic organizers, outlining passages, highlighting, and paper cutting/ folding, etc.

254 Using different learning materials: Learning materials like calculators/talking calculators, Taylor frame, abacus, Braille, geometrical kit, Tactile board, Tactile graph sheet (for bar-graph, histogram etc), 3-d blocks and figures, flash cards or pictures on paper, posters, chalkboard, projection screens, computers, books on tape and computerized text reader, screen readers, voice synthesis, scanners, daisy books, multimedia gadgets like CDs, MP3s, talking watches and talking clocks, videos/movies, modeling material like clay, textured objects/raised line paper, games and puzzles, etc, can help all children with visual impairment learn. 4.6 Strategies of Curricular Adaptation for Different Subjects Mostly children with visual impairment learn with the help of the non- visual modes viz, touch involving real, concrete materials; listening, smell and taste. In addition they exhibit the following needs across all subjects at elementary level: ● Visual stimulation; ● Experiential learning (observational/experimental/factual learning); ● Incidental learning (learning that happens naturally in the environment); ● Understanding of concepts like

laterality (localization), time, position, size, shape, association, discrimination, sequence, quantity, sensations, emotions, actions, colors (to the best visual ability), matching and classifying; •

Visual perception - learning from pictures, visual diagrams-maps, charts, graphs, tables, etc. and; • Slower cognitive processing in the earlier years till coordination of senses has developed. Based on the above consideration following strategies can be adopted for teaching different subjects to children with visual impairment: 4.6.1 Mathematics To make the child learn the concept of 'Time', several real life examples can be given. When one is teaching the concept of 'Volume', group activity can be conducted. For example, take water bottles of two different sizes and make the children fill the bottles with water. One bottle can be filled with, say, three glasses of water while the other 255 may just take two glasses to fill. Hence the capacity of the first bottle is more. Children can take turns in filling the bottles, counting and recording. The concept of 'Money' can be taught by first introducing notes and coins of different sizes. Then organize fun activity like arranging game of being shopkeeper and customers and ask them to purchase items with the money given to them. The child with VI can explore the notes and coins tactually and repeatedly to understand the difference. Make use of different senses for teaching mathematical concepts, for example, auditory (verbal descriptions) and tactual (converting visual figures into embossed tactile figures). 4.6.2 Social Sciences / Natural Sciences As much as possible real experiences are to be provided to the children with visual impairment. To explain 'Function of roots', children can be asked to touch a plant uprooted just then and then a plant which is kept uprooted for few days. The child can differentiate between plants that are alive or dead. To differentiate between different animals, apart from tactile pictures or models, VI students can also be introduced to the sounds of the animals. To make the children aware of different types of material like glass, gold etc., they can be asked to touch and feel different textures and then help them talk about it. Different role-play and other methods could be adopted for understanding of judiciary parliament, assembly and other concepts related with social science. Involve students in exploring the environment using other senses like smell and touch and organise excursions, trips and visits for the students to historical places. 4.6.3 Language To help the child to start 'making sentence' about him/her, she can be allowed to experience by touch the physical attributes to help make sentences. For example, child can be asked to touch a warm cup and asked to make a sentence: 'the cup is hot'. Similarly, auditory input can be given by different sounds. For a visually impaired child, pictures should be explained verbally in detail like—what, who, where and when. Based on the comprehension, help them to summarize, give oral answers. Experience for understanding can be enhanced by tactile and kinesthetic input. For example, differences or similarities between lassi and tea. Use of acting, dramatization and role play helps the child to understand better.

256 4.7 Principles of Adaptation Students with visual impairment learn concepts by using their auditory, tactile kinesthetic and olfactory senses, with appropriate modification and adaptation. Adapted teaching aids, course content and methodology involve special approaches and presentation styles to provide them optimal learning experience. It also helps students with visual impairment to understand concepts and to develop social interactions with other students. Mani (1992) suggested that the necessary adaptations could be made through processes of duplication, modification, substitution and omission without changing the instructional objectives. These four principles could be widely used for adapting course materials or, conversion of books in accessible formats. Duplication of the content or teaching materials should be carried out at most possible cases. It is just copying things with originality in accessible format (eg. Braille, Large print). When, duplication is not possible one can proceed for modification in the content. If modification is also not possible then content or material could be substituted with other which are as per needs of students with visual disabilities. Omission is last and least priority option to just remove or omit the content which is creating any hindrance in learning or could not be even substituted with other content or material. Duplication Degree of Participation

257 Ebeling, Deschenes & Sprague (1994) suggested nine types of adaptations in their publication 'Adapting curriculum and instruction' from Institute for the Study of Developmental Disabilities. These nine types of adaptation strategies could be used for children with visual disabilities are as follows: i) Input Input suggests adaptation in the way instruction is delivered to the learner. For example, planning more concrete and substitute examples; provide hands-on activities; place students in cooperative groups. ii) Output This area allows adaptation in how the learner can respond to instruction in an educational setting. For example: allowing verbal responses for children with visual impairment instead of written response; allow students to show knowledge with hands-on materials. iii) Size This suggests the adaptation of the number of items that the learner is expected to learn or compete in the classroom as well as home assignment. For example: reducing the number of science terms a learner must learn at anyone time. iv) Time Adaptation in time permits or encourages teachers, administrators to adapt the time allotted and allowed for learning, task completion or testing. For example: individualizing a timeline for completing a task. v) Difficulty Adapt the skill level, problem type, or the rules on how the learner may approach the work. For example: Allow a calculator for math problems; simplify task directions; change rules to accommodate learner needs. vi) Level of Support Increasing the amount of personal assistance with specific learner also desirable or, sometimes become essential for children with visual impairment. For example: assigning peer tutors or extended teacher support.

258 vii) Degree of Participation Adapting the extent to which a learner is actively involved in' the task comes under this principle of the adaptation. For example : in geography, have a student hold the globe, while others point out the locations. viii) Alternate Goals Adapting the goals or outcome expectations while using the same materials could also be opted when above all seven principles are unable to bring desirable adaptation. For example: In social studies, expect one student to be able to locate just the states while others learn to locate capitals as well. ix) Substitute Curriculum Providing the different instruction and materials to meet a learner's individual goals could also be adopted when one to seven principles are unable to bring desirable modification. For example: Individualize a timeline for completing a task; pace learning differently (increase or decrease) for some learners. 4.8 Lets Sum up We can find that there is a changing nature of the student population and increased integration or students with special needs in mainstream education. It demands even greater flexibility in curriculum and creativity from teachers. Students with varying levels of abilities are now widely available in the classrooms. They cannot, and should not, be taught in the same manner as with other children. The curriculum assumes that institution or appropriate authority will adapt and interpret the curriculum where necessary to meet their own requirements. There is no fixed formula or procedure for adapting general education curriculum to meet each student's needs including children with disabilities. NCF, 2005 underlines the significance of making curriculum "an inclusive and meaningful experience for children" stating "this requires a fundamental change in how we think of learners and the process of learning." Without adaptations/ modifications, some children in the classrooms would never be challenged to perform

259 up to their potential, while others may not be able to ever experience success.

Such adaptations need, necessarily, to involve the whole institution's team avoiding the transfer of responsibilities. Curriculum adaptations can evolve various strategies for effective teaching in the classroom that takes into consideration the individual needs of all children including children with visual impairment. Broadly, adaptation could be understood in two categories. First is accessibility adaptation and second is pedagogical adaptation of the curriculum. Accessibility adaptation is about eliminating architectural barriers, whereas pedagogical adaptation is about changes in and methodological barriers in curricular area in children with disabilities. Adaptation could also think as per needs or different subjects like mathematics, science, social science and language. The necessary adaptations could be made through processes of duplication, modification, substitution and omission without changing the instructional objectives. These four principles could be widely used for adapting course materials or, conversion of books in accessible formats. Ebeling, Deschenes & Sprague (1994) suggested nine types of adaptations are as follows: ● Input ● Output ● Size ● Time ● Difficulty ● Level of Support ● Degree of Participation ● Alternate Goals ● Substitute Curriculum

260 4.9 Check your progress Solve following problems : 4.9.1 Match the table: Curricular Adaptation Adaptation Action Principle Output Adaptation in time Time different instruction and materials Size Adapting the goals or outcome expectations Alternate Goals adaptation in the number of items that the learner is expected to learn Substitute Curriculum Adapting the extent to which a learner is actively involved Degree or Participation adaptation in how the learner can respond 4.9.2 Choose correct Answer: i) Pedagogical adaptation involves a. Use of assistive devices in the classroom b. Using White boards c. Using appropriate methodology d. Changing Course ii) 'Input' in curricular adaptation principle is about a. Adapting instruction b. Adapting student response 4.10 Reference • Lowenfeld, B. (1971). Our blind children: Growing and learning with them, Springfield, Charles C. Thomas • Aggarwal, J.C (2005) Curriculum development 2005. 263 5.1 Introduction You must be aware with the term curriculum. Curriculum is the heart of any educational system. It refers to the all lessons, academic content taught and other activities carried out in a school or in a specific course or programme. The children with visual impairment should have access to the core curricular activities for which they need to learn expanded core curriculum, which are specifically designed to meet unique needs of children with visual impairment.

In order to master these subjects, and to eventually live and work independently, students with visual impairment must learn an additional set of skills under expanded core curriculum.

Essential life skills including social interaction, independent living, career education, and communication modes must be taught alongside basic academics. Recreation, leisure, games and sports are also key components of the expanded core curriculum for healthy life and overall development. Adapted physical education and creative arts also form a part of this domain. Certain curricular adaptations and modifications are required for students with visual impairment to access visually oriented ideas. In this unit you will be oriented with different recreational activities and necessary adaptation thereof for the children with visual impairment.

5.2 Objectives: We know that curricular activities under expanded core curriculum is important for children with visual impairment. In this unit we will explore the need, importance and facilities available for recreational activities including yoga, games and sports for children with visual impairment as part of curricular activities. When you will complete this unit, you will be able to:

- Sensitize about recreational activities for children with visual impairment as part of curricular activities.
- Demonstrate techniques of teaching functional recreational and physical education skills.
- Explain importance and components of recreational skills development for children with visual impairment.
- Illustrate how physical education and creative arts activities can be adapted for the children with visual impairment.

264 • Understand the role of organisations in promotion of games and sports among the persons with visual impairment.

5.3 Curricular activities - Meaning and Need for Adaptation You can envisage curriculum from different perspectives. What societies envisage as important teaching and learning constitutes the curriculum (

UNESCO, 2016). However, at classroom level curriculum may be altered through a range of complex classroom interactions, and what is actually delivered.

In some cases, people see the curriculum entirely in terms of the subjects that are taught, and as set out within the set of textbooks, and forget the wider goals of competencies and personal development. Further, a curriculum framework is important

to

sets the subjects within this wider context,' and shows how learning experiences within the subjects need to contribute to the attainment of the wider goals.

All these issues form a curriculum system

which works as guiding function for education agents and stakeholders. The involvement of stakeholders (especially of teachers) in the development of the curriculum is of vital importance for ensuring ownership and sustainability of curriculum

activities (UNESCO, 2016). The activities pertaining to the school curriculum may be referred to as curricular activities.

Such activities are part and parcel of the instructional and other educational programmes entirely handled by the school staff. Curricular activities include all activities of classroom interaction for improving knowledge, physical education for fitness and recreational activities for harmonious integrity of mental and physical energy of the children. Curricular activities including all co-curricular activities are equally important for all round development of the students.

Children with visual impairment need systematic and purposeful instruction beyond the general education curriculum to gain the skills necessary to be independent, productive, educated members of society.

Recreational activities are one of the important aspects of curricular activities for students with visual impairment.

Although planning is necessary to include students in the recreational programme as it is an important component of the standard curriculum. In order to make the programme accessible to students, there are adaptations and specialized equipment. These may need to be employed to ensure access with full enjoyment of the recreational programme. Prior to determining appropriate adaptations, it is also important to first understand the functional vision of the student.

However, there should be effort to make instructional component as organized as possible for students with any visual impairment.

265 5.3.1 Recreation, Leisure, Games and Sports in Curriculum Recreation and leisure both terms are used to represent what people choose to do in their free, unobligated time.

Leisure time is any free time that can be used to pursue personal interests whereas recreation is an individual's preferred pleasurable and enjoyable activities in which they engage during leisure time (Expanded Core Curriculum Advocacy, 2016).

Recreation is a highly social phenomenon organized around friendships or family groups, and these social interactions buffer the effects of stress on health.

Recreational activities can be sedentary in nature, like knitting, chess, playing musical instruments,

and even

social networking in person or on the computer devices.

It can also be active and enhance physical fitness and well-being.

Recreation, fitness, and leisure are some of the instructional areas that need to be addressed. Knowledge of recreation, fitness, and leisure provides critical supports to a wide range of student capacities in the areas of social interaction, orientation and mobility, independent living, and self-determination. Developing recreation, fitness, and leisure skills can have far reaching positive effects on the lives of persons with visual impairment. Research has shown that recreation is an important factor in quality of life for everyone, including people with disabilities (

Expanded Core Curriculum Advocacy, 2016).

Participating in recreation, fitness, and leisure helps children with visual impairment develop social, career, and problem solving skills. Engaging in this area also increases self-esteem, self-determination, and overall health (

Dignan, 2012). Even if children with visual impairment choose not

to participate in every sport or recreation activity on their own time, they should learn what the rules are and how to play them (Lieberman, 1996). Knowing the rules of different games and keeping well-informed of sports offers a student with visual impairment opportunities for social interactions with peers.

Do you know? How Game is different from Sports? A game involves more than one person and a sport pertains to only an individual's skills and performance. In a sport, it is the sportsperson or the individual who determines the outcome.

Whereas, an individual's talent does not much determine a game. It is the entire

266 performance of the players that determines the winner in a game. Another difference is that sport is based on physical energy and the game is based on mental strength. How Leisure is different from Recreation? Leisure is the spare or rest time in the daily life of a person when he is not occupied by work, studies, sleep etc. Recreation is indulging in thrilling and exciting activities, to derive some pleasure and have fun in one's leisure time. While some people just take rest, sleep, watch TV, or play video games on computer in their leisure time, there are many who like to go out for recreation and indulge in activities like cycling, hiking, sailing, surfing, swimming, fishing, etc to have some fun.

5.3.2 Need for Adaptation You might be aware that the core

curriculum designed for children is generally appropriate for visually impaired children. However, some adaptations to the learning materials and the teaching approaches have to be made so that the learning needs of visually impaired children can be met.

Similarly, adaptation in recreational activities is important and hence recreational materials and strategies to be modified by considering needs of children with visual impairment. To teach recreational skills to children with visual impairment, we should adopt a consistent, realistic and flexible approach in extended core curriculum planning and implementation.

Due to limitation in visual sensation

recreation and fitness for children with visual impairments cannot be learned by passively observing others at play or by imitation.

Recreation must be intentionally and systematically taught with disability-specific techniques and safety in mind. The foundation for recreation can be learned in physical education,

games or, sports period with necessary accommodations and adaptations.

The teaching of recreation and leisure skills to blind and

visually impaired students must be planned and deliberately taught, and should focus on the development of life-long skills.

5.4 Adaptation of Recreational Activities As with other students, students with visual impairment need to be actively involved in recreational activities that teach lifelong skills to maintain their health. In order to make the activities accessible with full enjoyment necessary adaptations are required in the activities. Prior to determining appropriate adaptations, it is important to first understand the student's functional vision. The adaptation could be carried out in individuals; the

267 activities and rules; and the equipment for the recreational activities. Always begin with the smallest amount of adaptation that will ensure desired performance and success (Lieberman, 1996). Following issues need to be considered when making adaptations at different level:

- The Individual
 - o Involve the individual in determining adaptations
 - o How does the person ambulate? (Try to explore)
 - o Is the activity age appropriate? (Try to explore)
 - o What are the individual's characteristics and preferences? (Try to explore)
 - o What are the individual's favourite recreational activities? (Try to explore)
 - o Limit or add responsibility
 - o Modify demands on the student
- The Activity
 - o Make the area larger or smaller
 - o Make visible boundaries
 - o Orient the individual to the activity area
 - o Change the rules of the game
 - o Increase the tactile cues
 - o Change the number of players
 - o Decrease time of activity or add rest periods
 - o Slow the pace
- Playing Object
 - o Make the object bigger or smaller
 - o Make it softer or harder as per need
 - o Make it audible or bright as per need
 - o Change the texture of the object
 - o Make the object heavier or lighter as per need
 - o Increase the size of the target (like Basket of Basketball)

268 • Other Considerations

- o What to make the student more successful? (Try to explore)
- o Will the individual achieve success with minor adaptations? (Try to explore)
- o How can you add a cognitive component to the game? (Try to explore)
- o How can you ensure peers or siblings will also enjoy the activity? (Try to explore)

The instruction of recreation skills should be planned and deliberately taught. Often students who are visually impaired do not experience the same opportunities for recreation that students with no vision loss have in the early years. Recreational and leisure activities can provide an avenue for the development of motor skills, social skills, language skills, and fitness. It is important to expose the students to as many age- appropriate recreational activities as possible. This will best prepare the student for future inclusion and independence. There must be the inclusion of students with visual impairment in group activities. It should make sure that students play and talk with classmates rather than sit on the sidelines. During games, they should be allowed to buddy-up with other partner (preferably, a sighted partner). The visually impaired student should be able to participate in most recreational activities except for those that require good visual acuity. A student with a disability has an equal right to membership of the same group as all other students (NCF, 2006).

5.4.1 Physical Education In institutionalized school education, generally the main goal has been developing childrens' cognitive capacity in the sense of learning knowledge in academic disciplines. Physical education as part of education provides the opportunity for all children to learn about physical movement and engage in physical activity. Physical activity has also been associated with psychological benefits

269 in students by improving their control over symptoms of anxiety and depression. Similarly, participation in physical activity can assist in the social developing of students by providing opportunities for self-expression, building self-confidence, social interaction and integration. It has also been suggested that physically active young people more readily adopt healthy behaviours and demonstrate higher academic performance at school (WHO, 2008).

Students who are blind or visually impaired also need to experience physical activity. The visually impaired student with additional disabilities should experience a programme designed to improve

to improve their fitness levels by participating in various games, activities and exercises.

A regular physical activity programme will improve fitness and give the student with visual impairment

confidence to move through space without instructions. It can also develop motor skills needed for daily living and mobility (

Letcher, 2006).

5.4.2 Yoga

You might be aware with the term Yoga. Now, we will discuss the ancient Indian exercise system 'Yoga' and its implications for children with visual impairment. The word "Yoga" is derived from the Sanskrit root word 'yuj' which means 'to unite'. According to Yogic scriptures, the practice of Yoga leads to the union of individual consciousness with universal consciousness. It is now established as an art and science for healthy living. Yoga emphasizes stretching muscles and working to increase each individual's range of motion. Yoga is essentially a spiritual discipline based on an extremely subtle science which focuses on bringing harmony between mind and body. It also refers to an inner science comprising a variety of methods through which human beings can achieve union between the body and mind to attain self-realisation. The aim of Yoga practice is to overcome all kinds of sufferings that lead to a sense of freedom in every walk of life with holistic health, happiness and harmony (Ministry of Ayush, 2015). Yoga for Children with Visual Impairment Yoga is uniquely appropriate for people with visual impairment as it requires no or very less equipment. Yoga emphasizes stretching muscles and very useful to increase range

270 of motion in children with visual impairment. After some postures and stretches are learned, the children with visual impairment can work alone at home or continue with a class. Yoga may have a positive long-term impact on their life and living. Yoga improves the body posture and body awareness of children with visual impairment. It also increases body strength, flexibility and balance as well as confidence. Old habits of movement (mannerism) may also change by improved body awareness. As it has been discussed earlier that Yoga not only works for body but it also enhances body-mind unity. Concentration on the breath and movements is a concrete experience in mental focus. Hence, it induces ability to understand the self in a better way. Teachers should make a conscious effort to create a supportive approach with each individual student to learn yoga. There should be no competition or comparison between class members. In order to teach yoga successfully to people with visual impairment, the usual teaching methods is to be without depending on strictly visual demonstrations.

5.5 Adaptation of Games and Sports

You have found that the adaptation in games, sports and other recreational activities are important. We can discuss adaptation under two groups 1) Indoor Games and 2) Outdoor Games.

5.5.1 Indoor Games for Children with Visual Impairment

There are several indoor games available for Children with Visual Impairment including Chess, Playing Cards, Musical Toys and Computer Games etc. a. Chess Chess is a game of mind. It

is about boosting the self-esteem and the confidence of the persons with the visual impairment. Chess is available with few physical modifications in the chessboard and pieces. All the black squares are raised (about 3-4 mm) above as comparison to the white squares. Each of the chess pieces has a downward projection at the base to fit into the squares

271 on the Board having a hole in the centre of each square. All the black pieces have a pin fixed on their heads. The touch of the pin on the pieces helps the player distinguishing a white piece from a black one. The player is therefore able to play chess with having a clear picture in his mind of the position on the Board.

b. Playing Cards Playing cards is a very popular indoor game across the world. Playing cards can be enjoyed by persons with visual impairment with minor adaptation. The specific code could be created in Braille at left upper corner of each card. Playing cards can be enjoyed with similar intensity as by any other person.

c. Computer Games There are several computer games which can be enjoyed by the children with visual impairment with the help of screen readers. Many learning recreational tools facilitating leaning with fun are also available for these children.

5.5.2 Outdoor Games for Children with Visual Impairment

You can also find several games available for Children with Visual Impairment including Cricket, Gymnastics, Martial Arts, Running and Tug-of-war etc. a. Cricket Cricket in India is very popular and visually impaired in this country are no exception. The visually impaired are equally passionate about cricket.

Blind Cricket is a version of the sport of cricket adapted for blind and partially sighted players.

The sport that is being played since the 1920s.

The rules of blind cricket are based on the standard laws of cricket with some essential modifications.

In terms of playing equipment, the major adaptation is the ball.

National Institute for the Visually Handicapped (NIVH), Dehradun, developed the audio ball that is now accepted as the international standard. This ball is made of hard plastic with ball bearings inside.

The stumps are made of hollow steel pipes welded into one set, to enable totally blind players to touch it in order to correctly align himself when batting or bowling also to produce a sound when struck by a ball.

272 (

Picture Source: World Blind Cricket Council)

5.6 Creative Arts for the Children with Visual Impairment

Art is important for children especially during their early development. Research shows that art activities develop brain ,capacity in early childhood. As children progress into elementary school and beyond, art continues to provide opportunities for brain development, mastery, self-esteem and creativity. Creativity is expressing one's own idea, trying new things, and experimenting with changing materials. The best way to develop creativity is to provide a variety of materials, and give children time to create on their own. Art activities for children introduce them to new tools and materials, and possible ways to use them.

People tend to think that creating art is a purely visual process. Whereas, blind or visually impaired children take part in art class on equal terms with their sighted classmates.

Children express how they feel and think about the world through their art, which gives them a way to express the feelings and ideas that they don't have the words to talk about. Art helps children to develop a sense of their own individuality, a sense of self-respect, and an appreciation for others' work. As children draw, paint, and make collages, they are learning about the world (colour, shape and size of objects). When they use paints, glue, and markers, children are planning,

273 experimenting, and problem solving. As children mix paint, they learn to understand cause and effect. Art gives children chances to make decisions, and to learn from the experience of making choices about their art work

(Mincemoyer, 2016). 5.7 Agencies/Organizations promoting Sports, Culture and Recreation There are several organisations across the world working for betterment of sports facilities for persons with disabilities. Here you will find some major organisations and agencies working for promotion of sports and recreational activities among persons with visual impairment. 5.7.1 Indian Blind Sports Association Indian Blind Sports Association (IBSA)

is the largest national level sports body devoted to the promotion of sports among the visually challenged in the country.

The Association was established in April 1986 through the initiative of the Blind Relief Association, Delhi (BRA).

The Association is recognized by the Indian Olympic Association and affiliated to the International Blind Sports Federation

and

the

Paralympic Committee of India. Indian Blind Sports Association has been organizing National Sports Meets for the

Blind once every two years. These National Sports Meets, which include athletic events like races, long jump, javelin and discus throws, shot put, swimming along with indoor game event of chess. 5.7.2

Chess Federation of India

The All India Chess Federation (AICF) is central administrative body for the game of chess in India. Founded in 1951, the federation is affiliated to Federation Internationale des Echecs (FIDE), the world body for chess.

Its current headquarters is in Chennai.

The All India Chess Federation for the Blind (AICFB) is the national body for the game of Chess among visually impaired in India.

AICFB is also affiliated to All India Chess Federation (AICF) which is recognized by Government of India.

The All India Chess Federation for the , Blind (AICFB) was established in 1997 with the objective of promoting the game of chess among the visually impaired all over the country.

The AICFB is affiliated to the International Braille Chess Association (IBCA).

274 5.7.3

Paralympic Committee of India

The Paralympic Games is a major international multi-sport event, involving athletes with a range of physical disabilities and intellectual impairment.

This includes athletes with mobility disabilities, amputations, blindness, and Cerebral Palsy.

All Paralympic Games are governed by the International Paralympic Committee (IPC). The International Paralympic Committee (IPC) is the global governing body of the Paralympic Movement. Its purpose is to organise the summer and winter Paralympic Games and act as the International Federation for nine sports, supervising and coordinating World Championships and other competitions. It was founded on 22 September 1989 as a non-profit organisation, it is based in Bonn, Germany and aims to develop sports opportunities for all people with an impairment from the beginner to elite level.

Paralympic Committee of India (PCI) is the body which is responsible for selecting athletes to represent India at the Paralympic Games and other international athletic meets and for managing the Indian teams at the events. The organisation was founded in 1992 as the Physically Handicapped Sports Federation of India. 5.7.4

Abilympics

Abilympic are vocational skill competitions for persons with disabilities to enable them to showcase and enhance their talent. Abilympic empower the contestants and help create public awareness about their abilities. The

title "Abilympics" was coined from the phrase "Olympics"

of Abilities." The first international abilympic was held in Tokyo in 1981 to International Abilympic Federation commemorate the United Nations' International Year of Disabled Persons. During this second international abilympic at Colombia, it was proposed to establish an international organization in order to promote the international abilympic and to hold it on a regular basis. Hence, the International Abilympic Federation (IAF) came into existence during the third international abilympic held in Hong Kong. Since then, the international abilympic has been held in Perth, Australia (1995), Prague, Czech Republic (2000), 275 Delhi (2003), Shizuoka, Japan (2007), Seoul, Korea (2011) and Bordeaux, France (2016). 5.7.5 World Blind Cricket Council is an administration of blind cricket to manage cricket for persons with visual impairment

at international level. The WBC was established in September 1996 WM (when a meeting was held in Delhi to promote and control the blind cricket globally. George Abraham

from India was the founding chairman of WBC. 5.8 Let us sum up

Curriculum refers to the all

lessons, academic content taught, other activities in a school or in a specific course or programme. The activities pertaining to the school curriculum may be referred to as curricular activities. Curricular activities include all activities of classroom interaction for improving knowledge, physical education for fitness and recreational activities for harmonious integrity of mental and physical energy of the children. The children with visual impairment should have access to the regular core curriculum for which they need to learn an expanded core curriculum, which are unique to visual impairment. Essential life skills including social interaction, independent living, career education, communication modes and recreational activities are key components of the expanded core curriculum. Recreational activities are one of the important aspects of curricular activities for students with visual impairment. In order to make the programme accessible to students, there are adaptations and specialized equipment. Prior to determining appropriate adaptations, it is important to first understand the student's functional vision. The adaptation could be brought out in three domains first in the individual and second in the game rules or activities and third in the playing equipment. Physical education and yoga as part of education provides the opportunity for all children to learn about physical movement and engage in physical activity. Yoga is a spiritual discipline based on an extremely subtle science which focuses on bringing harmony between mind and body. Yoga is uniquely appropriate for people with visual impairment as it requires no or very less equipment. Yoga improves the body posture and body awareness of children with visual impairment. It also increases body strength, flexibility and balance as well as confidence. There are several indoor games (including Chess, Playing Cards, Musical Toys, and Computer Games etc.) and outdoor games (including Cricket, Gymnastics, Martial Arts, Running and Tug-of-war etc.) available for Children with Visual Impairment. Several organisations across the world are working for promotion of sports and recreational 276 activities among persons with visual impairment.

Indian Blind Sports Association (IBSA)

is the largest national level sports body devoted to the promotion of sports among the visually challenged in the country. The

All India Chess Federation for the Blind (AICFB) is the national body for the game of Chess among visually impaired in India.

Whereas,

World Blind Cricket Council is an organisation of blind cricket to manage cricket at international level. 5.9 Check your Progress 5.9.1 Match the table: Organization Place World Blind Cricket Council Chennai International Paralympic Committee (IPC) Delhi All India Chess Federation (AICF) Germany Indian Blind Sports Association (IBSA) UK 5.9.2 Choose correct Answer: i) Cricket ball for visually impaired is a. Red and Solid b. Black and Hollow c. White & with Sound d. Black and with Sound ii) Chess is a game related with a. Hearing ability b. Kinesthetic skill development c. Speaking d. Mental orientation 5.9.3 Answer the questions: i) What are the adaptations made in cricket for visually impaired?

277 ii) Enlist various indoor and outdoor games for children with visual impairment with their advantages and limitations. iii) How could Yoga be beneficial for children with visual impairment? iv) Give detailed description about role of organization or institutions in promotion of recreational facilities for children with visual impairment. 5.9.4 Let's Explore i) How is physical education different from yoga? ii) What is difference between Recreation and Sports? iii) Plan to adapt a new game for children with visual impairment. iv) Make a plan for teaching yoga to children with visual impairment and execute it in small group. 5.10 References Dignan, K. Netaji Subhas Open University From the Vice-Chancellor's Desk Dear Students, from this Academic Session (2015-17) the Curriculum and Course Structure of B. Ed.- Special Education have been thoroughly revised as per the stipulations which featured in the Memorandum of Understanding (MoU) between the Rehabilitation Council of India (RCI) and the National Council for Teacher Education (NCTE). The newly designed course structure and syllabus is comprehensive and futuristic has, therefore, been contextualized and adopted by NSOU from the present academic session, following the directives of the aforesaid national statutory authorities. Consequent upon the introduction of new syllabus the revision of Self Instructional Material (SIM) becomes imperative. The new syllabus was circulated by RCI for introduction in the month of June, 2015 while the new session begins in the month of July. So the difficulties of preparing the SIMs within such a short time can easily be understood. However, the School of Education of NSOU took up the challenge and put the best minds together in preparing SIM without compromising the standard and quality of such an academic package. It required many rigorous steps before printing and circulation of the entire academic package to our dear learners. Every intervening step was meticulously and methodically followed for ensuring quality in such a time bound manner. The SIMs are prepared by eminent subject experts and edited by the senior members of the faculty specializing in the discipline concerned. Printing of the SIMs has been done with utmost care and attention. Students are the primary beneficiaries of these materials so developed. Therefore, you must go through the contents seriously and take your queries, if any, to the Counselors during Personal Contact Programs (PCPs) for clarifications. In comparison to F2F mode, the onus is on the learners in the ODL mode. So please change your mind accordingly and shrug off your old mindset of teacher dependence and spoon feeding habits immediately.

I would further urge you to go for other Open Educational Resources (OERs) - available on websites, for better understanding and gaining comprehensive mastery over the subject. From this year NSOU is also providing ICT enabled support services to the students enrolled under this University. So, in addition to the printed SIMs, the e-contents are also provided to the students to facilitate the usage and ensure more flexibility at the user end. The other ICT based support systems will be there for the benefit of the learners. So please make the most of it and do your best in the examinations. However, any suggestion or constructive criticism regarding the SIMs and its improvement is welcome. I must acknowledge the contribution of all the content writers, editors and background minds at the SoE, NSOU for their respective efforts, expertise and hard work in producing the SIMs within a very short time. Professor (Dr.) Subha Sankar Sarkar Vice-Chancellor, NSOU

Intervention of late identified children with hearing impairment : Challenges & Strategies

10 1.7.1 Challenges of

intervention 1.7.2 Habilitation Strategies 1.7.3 Traditional Approach 1.7.4 Wedenbery Approach 1.7.5 Ling's Approach 1.7.6 Ski-Hi Approach 1.8 Let Us Sum Up 1.9 Check Your Progress 1.10 References 1.1 Introduction An early intervention is very important aspect for management of any diseases or disabilities and the success of early intervention depends primarily on early identification of the disease or disability. The term early intervention is about taking action as soon as possible to tackle problems for children and families before they become more difficult to reverse. Early intervention involves identifying children and families that may be at risk of running into difficulties and providing timely and effective support. Generally early intervention is important for children to develop better social and emotional skills, communication, the ability to manage their own behaviour and mental health, a stronger foundation for learning at school, an easier transition into adulthood, better job prospects, healthier relationships and improved mental and physical health. Like other disabilities early intervention of hearing impaired children is also an important to develop better communication skill, better social and emotional skill, a stronger foundation for learning at school. The eventual language learning and educational success of any child with any type and degree of hearing loss whether unilateral or bilateral, depends on early diagnosis, early amplification, and early intervention. These three EARLY's must be all before age 2! Without these, children are at risk for both language and learning delays. Today's technology available has made it more easy to deaf and hard of hearing children than ever before. Having the ability to hear speech does not automatically ensure the development of good spoken language. However, there is much training that must take place over a period of time.

Parents and the special educator of HI children must take advantage of the prime "critical

11 age for learning language" of the first three years of life to give their children an auditory- oral approach to the development of spoken language. This includes using listening and speech - not signing - to develop the families' mother tongue. 1.2 Objectives Children born with any type of developmental delay are at risk for falling behind in their educational potential. When hearing loss is diagnosed, it is very important to begin the planning process for child's educational future. That is where early intervention services come in. Early intervention services are designed so hearing impaired children receive the early intervention or other services they need in a timely manner so they can enter preschool and elementary school ready to succeed. Studies have shown that the following three goals are vital to any early intervention plan: A service plan developed as early as possible after the child's diagnosis. Heavy involvement by families in the development and execution of the plan. A highly structured plan that provides clear and measurable goals. A child's brain is programmed to learn foundational language skills during the first six years of life, the first three years being the most critical.

After age 6, it is increasingly difficult for the human brain to acquire language and speech skills. Therefore, families who choose listening and spoken language for their children with hearing loss need to recognize that their child will need some degree of educational and (re)habilitative intervention, and then start taking steps in that direction as soon as they suspect their child has a hearing loss. The earlier the intervention, the easier it will be for the child to acquire listening and spoken language. As with every aspect of raising the child, parents full commitment and involvement in an early intervention plan is vital to the success of the child. Even with regular speech therapy, the vast majority of child's learning will take place with the parents at home. 1.3 Parent-infant programmes for children with HI 1.3.1: Overview The advancement

in hearing screening technology makes it possible to identify hearing- impaired infants

soon after birth and therefore increases the opportunity for early intervention. To provide services for families of hearing-impaired infants, the Parent Infant Program (PIP) was established. The importance for parent infant programme 12 emerged from the concept that, the most important learning environment for a child during the early years is the home and

during these early formative years, the child's most important relationships are with their parents and other primary care-givers, such as siblings, grandparents and other family members.

The children come out to the best of their abilities when their emerging speech, language and auditory skills are reinforced by their parents and other family members at home. The emphasis of PIP is a home-based, family-centered, parent-guided, child-specific, natural approach to learning. The parent infant program brings together children from infancy through pre-school age, their parents, family and a variety of early intervention professionals to work as a team and offer services to assist families in communicating and bonding with their children in the child's natural environment. Parents are encouraged to network with other parents. PIP helps hearing impaired children and their parents to develop their potentiality in primary areas and helps the child to develop his language, literacy skills, and growth in world awareness, positive self-esteem, and personal responsibility.

1.3.2: Need The Parent Infant Program offers parents and caregivers the skills and confidence they need to help their young children learn to listen and talk. Individualized sessions provided at home or in childcare settings are guided by teachers of the deaf and focus on auditory habilitation and speech/language development. The aims of parent infant programme are as follows:

- 1) To understand their child's deafness Parents must understand the basic of hearing mechanism and hearing loss. The information regarding hearing loss includes type and degree of hearing loss. Children with sensory neural hearing loss will have more adverse effect on language development than the conductive hearing loss. Degree of hearing loss also plays important role. Sever to profound degree of hearing loss will have great difficulty in developing language than mild or moderate degree of hearing loss. Even children with unilateral hearing loss may have some problem in the early stage of their life.
- 2) To monitor growth in their child's listening, speech and language skill. The Parent infant program also provides auditory habilitation services to the child which include fitting of appropriate hearing aid, to show parents how to use the hearing aid, and auditory training to develop listening skill with the parents so that the child learns to respond through hearing and increases his/her receptive and expressive language. Baseline audiological and language data on the children also helps to monitor the growth of listening, speech, and language skill of the child.
- 3) To help the parents to coordinate their child with medical personnel, equipment dealers, and school systems. The parents infant program is also designed to help parents to cordinate with medical personnel, mainly with Otorihnolaryngologist for any ear check up as and when required and with Paediatrician for general chek up. It also helps to cordinate with equipment dealer mainly with hearing aid dealer for after sale services of hearing instrument. Cordination with school system for mainstreaming of the child to normal school.

1.3.3: Requirement Early identification: Early identification and intervention with family support are important factors which determine the success of parent infant program for children with hearing impairment. Therefore whenever a hearing problem is suspected immediate action is imperative. Hearing impairment not only affects the child's speech and language development but also impedes the child's social, educational and personality development. If hearing impairment is identified early, these adverse effects due to hearing impairment in the child can be minimised. Drugs and surgery are useful in treating middle and outer ear problems. In case where the hearing impairment is irreversible, hearing aid fitting is recommended. Significant hearing loss is one of the most common major abnormalities present at birth. If undetected, it will impede speech, language and cognitive development. Significant bilateral hearing loss is present in 1 to 3 per 1000 new born infants in the well-baby nursery population. It is an established fact that if hearing loss is present it should be detected and remediated before the baby is 6 months old. A two-stage screening protocol is projected, in which infants are screened first with otoacoustic emissions (OAE). Infants who fail the OAE are screened with auditory brainstem response (ABR). Early intervention is about taking action as soon as possible to tackle problems for children and families before they become more difficult to reverse. The rehabilitation process includes training to make the best use of residual Hearing, speech reading instruction, speech-language stimulation and therapy and the services of special educators. Amplification devices: When babies are born, they are still developing their ability to use their senses, including hearing. Babies who can use at least some of their residual hearing will benefit from early chances to listen, provided by devices like hearing aids

14 or cochlear implants. Using these devices infant hears sounds louder and clearer. Not every baby born with a hearing loss can benefit from amplification, but most can. Parents need to make decision, what kind of hearing aid to select, and whether or not to consider a cochlear implant. To make any of these decisions, information may be gathered from many sources: professionals, other parents, and the Internet. Using of ear mould with the amplification devices are mandatory. A team of professionals: Parent infant programs require involvement of a team of professionals along with the parents. These include an audiologist, speech and language therapist, primary care physician, Special educator etc. From special educators, audiologist, speech/language therapist, parents can learn to see that the hearing aids are functioning optimally, care and maintenance of the hearing aids, can learn how to call baby's attention to sounds and what they mean. Parents also can learn how to make speech as audible as possible, and how to encourage infant to listen to his or her own voice as well as parents

Ensure hearing aids are used by the child. The professionals also advice parents to talk to the child most naturally preferably in a slightly slower manner ensuring that the child is looking at them, consciously label the things around the infant,

converse on all the incidents and activities going around him.

Team of professionals understand the emotions of parents therefore help them to make difficult decisions about their children's communication. Parents and other family members including caregiver play the main role in the team for a successful parent infant program. All children learn from their environment. Babies absorb language, thinking skills, and social skills as they experience the world with their caretakers and others. Most children acquire skills, especially language, effortlessly, because others are fluent in the language and use it all the time. Children who are deaf or hard of hearing can usually acquire language in the same way as hearing children, but they will not know that people around them are using language unless they have a teacher and parent/family members who can help them access the language environment. Once the baby is diagnosed as hearing impaired, it's the parents who have to take all the decisions from amplification device, mode of communication to be used to school placement. They have to develop the listening skill of their baby, they have to provide adequate language and stability of their child and so on. Appropriate listening situation: Parents can make their house a good listening environment. If possible one of the room can be made acoustically appropriate for the hearing impaired infant where formal way of training can be done by the parents. Finding appropriate amplification is just the beginning, however. Because hearing aids and cochlear implants work differently than glasses, or ears with normal hearing, infant will

15 need parents to guide those early listening experiences Training materials: Training materials include toys and books, tools for listening training such as different noise makers and instruments generate different frequency tone. 1.3.4: Plan of action It is possible to identify hearing-impaired infants at birth with advances in hearing screening technology therefore enhancing the opportunity for early intervention. The Parent Infant Program (PIP) was established to provide services for families of hearing-impaired infants. It is assumed that children advance to the best of their abilities when their emerging speech, language and auditory skills are reinforced by parents during early years and there the enthusiasm for PIP emerged. The most important learning environment for a child during the early years, is the home.

During these early years, the child's most important relationships are with his or her

parents and other primary care-givers, such as siblings, grandparents and other family members.

Therefore, the emphasis of PIP is a home-based, family-centred, parent-guided; child-specific which is a more natural approach to learning. The parent infant program brings children from infancy through pre-school age, Parents, other family members and early intervention professional work as a team and offer services in communicating with their children in the child's natural environment. Parents are encouraged to network with other parents. Parent infant program helps hearing impaired children and their parents to develop potential in primary areas and nurture the child to develop language skills, better social and emotional skills, the ability to manage their own behaviour and mental health, a stronger foundation for learning at school, an easier transition into adulthood, better job prospects, healthier relationships and improved mental and physical health.

Language development is vital as it is the basis of communication. It is the most important factor in the all-round development of a child. It is the basis of most learning, not only in the formal aspects of education, but also in the development of character, emotional state and social relationship of the children. The questions are 'who should develop language and how it should be taught to the children'. In order to answer both these questions the simplest thing is to recollect how hearing babies have acquired language. The hearing baby acquired or learnt it from the parents and the family members around them through constant exposure and interaction. Parents unconsciously teach and reinforce the language. It is an established fact that the hearing impaired child also has the same innate capacity to learn language as a hearing child but the reason that he has not learnt it, is because he has not heard the language around him.

16 Parents of a hearing impaired child may therefore interact and talk to him as naturally as they would do with hearing children.

Action plans are designed based on short term and long term goals. Parents of a hearing impaired child should interact and talk to their child

as naturally as they would do with hearing children. They should remember

To see that

hearing aids are used by the child. That the hearing aids are functioning optimally. Talk to the child most naturally preferably in a slightly slower manner ensuring that the child is looking at you. Consciously label the things around him. Converse on all the incidents and activities going around him. Throughout the day there are plenty of ideal moments to give a hearing impaired child an opportunity to acquire language, these are: getting up, washing, bathing, dressing, undressing, cooking time, meal time, going out to the market garden or zoo, visiting friends, playing, going to bed etc.. These are the times when the phrases used have real meaning and so the parents could

plan to help in developing

vocabulary, meaningful language structures and communication skills in the hearing impaired child.

The following examples of the action plan will describe some of the ways to help parents and their family at home. Work with parents and other family members to identify priority needs for the child and family. Evaluate the child's strengths and current developmental skills. This information will be used as base line of PIP Plan. This document is like a road map. It will guide parents and specialist for learning and growing of the baby. Work closely with family to address priority goals you have set for yourselves and for the baby. Specialist will work with parents to evaluate the progress you are making and to set new goals. Support parents in communicating with their baby and encourage in baby's development through natural daily routines. To provide support and resources as families work to cope with and understand the diagnosis of hearing loss. Assist parents and family members in identifying sources of support, if this would be of help to them.

17 Recognize expertise of the parents and other family members and develop a comfortable and effective partnership with them. Become a resource to parents and other family member as they search for answers and how best to help their baby to learn Help parents and their family to choose the best methods of communicating with their baby, provide support in evaluating how the child is responding and in making decisions about communication approaches. Not all children with hearing loss learn in the same way. Watch as parents interact naturally with their baby, pointing out the many positive things parents already do to support their baby's learning and suggests additional techniques to encourage the baby's listening, babbling, watching and learning. 1.4 Pre-school training programmes 1.4.1 Overview: Children born with hearing loss are at risk for falling behind in their educational potential. When hearing loss is diagnosed, it is very important to begin the planning process for the child's educational future. Children receive the early intervention or other services they need in a timely manner so that they can enter pre-school and elementary school with an ease. The pre-school program starts for children from three to approximately five years of age. The school provides a language intensive program with a curriculum especially designed for children with hearing loss. It is designed with the aim of intensive small group language/listening teaching. The speech pathologists, classroom teachers and teaching assistants work as a team to track the children's vocabulary, listening skills, speech, syntax, and discourse skills. Children alternate between small group language lessons and larger group content specific lessons. The aims of pre-school training program are as follows: Children will be using complex sentences by the time they are ready for mainstreaming.

Children's receptive and expressive language ages will be within one year (or less) of their chronological ages Children will develop oral narrative skills Children will develop Theory of Mind skills

18 Children will continue developing pre-reading skills Children who meet age requirements to attend kindergarten will have their readiness skills assessed If the gap between language age and chronological age is closed, the children only need to keep up when they get into mainstream, and not catch up. The pre-school training covers all essential areas of early childhood development like self-help, cognitive, motor, and social with special emphasis on language skills development. The pre-school training programme is backed with development and on-going up gradation of the curriculum for training in different skill areas and in different languages. It Supports for successful mainstreaming of children passing out of pre-school and follow-up services. Pre-school training program also helps to develop of varied innovative teaching-learning aids for pre-school children for skill training in different areas (visuals, manipulative models, educational play materials, and interactive multimedia materials). Apart from providing preparatory services to children with communication disorders, preschool is also involved in capacity building of important stakeholders involved in education of children with communication disorders like trainees from related professional fields and caregivers.

1.4.2 Need: The ultimate goals of pre-school functions are of catching children with communication disorders early and provide all-round development, as well prepare them for mainstreaming. With this intention, the pre-school aspires to: Provide early stimulation and developmental training in all areas of early childhood development. Provide effective pre-school training that prepares children with communication disorders for successful schooling, especially in mainstream learning environments. Provide stimulating learning environment appropriate for young children with communication disorders with ideal adult: child ratio. Empowering caregivers of children with communication disorders through Practical training for diploma, undergraduate and post-graduate students from the fields of speech and hearing, and special education. Training for parallel teaching, side by side with teaching in pre-school. Periodic orientation programmes for enriching parent knowledge and skill on various topics related to training children with communication disorders. Practical training in developing special teaching learning material for children

19 with communication disorders. Provide space for manpower training in related fields like speech and hearing, and special early childhood education among others.

1.4.3 Requirement: The pre-school should be equipped to enable communication as well as all-round development of children including assistive listening devices such as different class room amplification devices like group hearing aids, FM hearing aids; audio-visual aids like multimedia projector, 52" television; elaborate outdoor play equipment that facilitate therapeutic and academic training; and several computers along with wide range of educational CDs and software for developing multimedia educational materials. Following are the requirement for a successful preschool program.

Amplification devices: Children must use individual amplification devices whether hearing aids or cochlear implant. Children who can use at least some of their residual hearing will benefit from early chances to listen, provided by devices like hearing aids or cochlear implants. Using these devices children hear sounds louder and clearer. Parents need to make decision, what kind of hearing aid to select, and whether or not to consider a cochlear implant. Using of ear mould with the amplification devices is mandatory. Children also use different class room amplification devices in the class for their group activities.

A team of professionals: Pre-school training program for hearing impaired children requires involvement of a team of professionals along with the parents. These include an audiologist, speech and language therapist, primary care physician, Special educator etc. From special educators, audiologist, speech/language therapist, parents can learn to see that the hearing aids are functioning optimally, care and maintenance of the hearing aids. Parents also can learn how to make speech as audible as possible, and how to encourage children to listen to his or her own voice as well as parents ensure hearing aids are used by the child. The professionals also advice parents to talk to the child most naturally preferably in a slightly slower manner ensuring that the child is looking at them, consciously label the things around the infant, converse on all the incidents and activities going around him.

Team of professionals understand the emotions of parents therefore help them to make difficult decisions about their children's communication.

While these activities are continuously going around at home parents should pay sufficient attention to the following:

20 Take the help of special teachers to plan out the educational programme of the child.

Be a part and parcel of his/her daily lessons at school and inculcate listening, speech reading and reading skills. Meet the school teachers as often as possible to carry over and to follow up classroom teaching. Learn the techniques used by the teachers in the class-room to teach language and follow them at home. Discuss about your queries and doubts with the teachers. Also discuss any intimate daily happening, celebrations, outings within the family so that there is a carryover of the same in the class-room teaching. Be more supportive to the child in his success as well as in failures. Be a teacher and facilitator for learning and make the child independent and self-sufficient. Motivate the child to interact with everybody around him. Inculcate good values and develop a sound moral character in the child. Help the children express themselves freely and involve them in all family interactions. Participate as equal partners in the education of your - children.

Appropriate listening situation: The pre-school training set-up should have a good listening environment for the hearing impaired children. If possible all the rooms can be made acoustically appropriate for the hearing impaired children where formal way of training can be done. If induction loop systems are used as assistive listening device proper steps must be taken to avoid any spill over effect. Training materials: Training materials include toys and books, tools for auditory training such as different noise makers and instruments generate different frequency tone. Audio-visual aids like multimedia projector, ; elaborate outdoor play equipment that facilitate therapeutic and academic training; and several computers along with wide range of educational CDs and software for developing multimedia educational materials.

1.4.4 Plan of action

Class room activity

Pretend Play Children who are deaf have normal intelligence and can study just like other children. However, in the initial years, they struggle with many issues including language and communication. Activities for the classroom are suggested to help a child build up language, communication and social skills. Pretend play is a normal part of child development. Most children pick up dolls, talk to them, and play with them. Children with sign language use signs instead of talking. Provide opportunities for the child to pretend play. Provide materials, time and space for a child to practice communication skills with dolls and imaginary friends. If the child is not doing it on their own, you may need to model it and involve the child till he or she learns.

Classroom Responsibilities In the classroom, children who are deaf should also be given some responsibilities. Responsibilities can be as simple as making sure the board is clean before they leave, or opening the windows in the morning. These responsibilities help the child feel important and valued and helps build up their confidence to work independently.

Story Time Story time is a great way to develop language skill in children with hearing impairment. Activities should use short stories with pictures and few words per page. Read the words, and explain them during the story. Get the children to sign some of the words used in the story with you. Also, use the story to talk about other things related to the same topic. Even if you have an integrated classroom, the other children will enjoy learning and practicing signs at story time. Allow children to look at books that you have read to them at their own pace.

Music Children who cannot hear miss out on learning to appreciate and enjoy music. However, you can make this possible by helping them understand vibration. Use drums and other vibrating instruments in your classroom for activities. Allow children to play with instruments and feel the vibrations. You can also play a drum while allowing the child to feel the rhythm with one hand, and follow the rhythm with the other hand on another drum.

Paired Activities Children who cannot hear find it difficult to work with others, especially other children who can hear. Pair up a child who is deaf with another child to do an activity together. The activity can be a craft activity, or even going to the garden and getting some materials for the lesson. Start with more structured activities that require only the sharing of

22 materials, and slowly involve the child in more unstructured activities that require planning and communication. All of these various activities will help a deaf child develop necessary communication skills. Parent Activities for Children with Hearing Loss Having a child with any disability is overwhelming. Hearing loss is no exception. Having a typical child is an enormous amount of work, as any parent can tell you, so the stress of having a child who requires extra work is understandable. For parents who choose listening and spoken language for their children with hearing loss there are some things that will help in developing speech, language and listening skills. Read to your child every day: For young children the goal is 10 books a day. As kids get older, at least 30 minutes. When kids learn to read, still read to them every day and try and read things that are a little more difficult than they can read themselves. Sing to your child every day: Parents don't have to be really good, they just have to be able to carry a tune. Singing provides a good sense of rhythm and the tone helps them recognize the melody in speech. Rhyming games: As kids get older, play rhyming games. Rhyming is very helpful in building phonics skills which is critical for reading. Play rhythm games: Clapping out rhythms is fun and a good skill to learn. Clap out a variety of different rhythms starting from something short (DaaDaDa) and building to more complex rhythms. Language of math: Math is really a language activity. For kids to succeed in math they need to learn the words of math problems. How do you know if the activity is an addition, subtraction, multiplication or division problem? How much more, howmany fewer etc., may be difficult to figure out. Many parents are not comfortable with math and may avoid doing math activities. Point out words: on packages, on signs, and around the house. Play "sound out the word" games when you see words that could be sounded out. Watch the sound in your house: Turn off the TV or radio during dinner. Don't have the dishwasher running while you are trying to talk. Background music is not helpful unless it is parent directed. Try to have everyone take turns speaking. It is hard to hear when two people are talking at the same time. Turn off the TV: Kids do not learn language from watching TV. They learn by interacting with people. So just spend time with them and talk talk talk.

23 Make hearing technology fun: It is not easy to be different. If we think about hearing aids as ear jewelry, pretty ears. etc. we will help kids have a positive view of their technology. Let them choose a color (my hearing aids are purple, not boring beige). If a child chooses a color or puts sparkles on his or her hearing aids, he will more likely become invested in it. Talk, Talk, Talk, Talk: Talk all day long. It is a lot of work, but it makes all the difference in the world. There is a lot of research that shows that the number of words a child has at age 4 is directly related to the number of words a child has heard. Since even with the best technology, a child with hearing loss will not be hearing everything, they need more input. So just talk talk talk talk talk. Describe everything you are doing. "I'm cutting up the tomatoes, cut, cut, cut. Now I am putting them into the frying pan. I am going to cook them. I am stirring. Would you like to stir?" It can definitely get exhausting, but keep trying to remember that what you put in is what will come out of your child. 1.5 Individual Speech and Language Therapy Program 1.5.1: Overview Individual speech and language therapy program helps in the identification, screening, assessment, and rehabilitation of individuals with hearing loss. Speech and language therapists have the specialist skills and training to address communication effectiveness, disorders, differences, and delays that result from a variety of factors, including those that may be related to hearing loss. They provide individualised assessment, diagnosis and intervention to the child and also help the parents to make the choices regarding communication mode and habilitation approach. Individual speech and language therapy program accelerate language development in order to reduce and/or eventually close the gap between the child's chronological age and language age. Individual speech and language therapy program helps to make the choice of mode of communication of the child such as auditory-verbal communication, Aural oral communication, cued speech, sign language or total communication. It helps parents to select hearing devices (analog hearing aids, digital aids, bone anchored hearing aids, cochlear implants) suitable for their children and teaches parents how to maintain and troubleshoot their child's hearing device(s) in order to get the best sound possible. Individual speech and language therapy program provides family-centred therapy that focuses on the child's learning needs and potential which helps the child to develop Skills and sub-skills for learning speech and language.

24 1.5.2: Need Children with hearing loss needs speech and language therapy because of the adverse effect of auditory deprivation on communication. Therefore an early intervention on speech, language development is important because of critical period for language learning and brain reorganisation. Children learn the following aspects of speech through the Individual speech and language therapy program. 1) Vocalization and its meaningful use 2) To improve the usage of meaningful vocalization more spontaneously. 3) Proper use of intensity and pitch in vocalization. 4) To improve on speech imitation skill. 5) Proper use of respiration and tongue. 6) Maximum use of residual hearing for production of Speech. 7) To teach the child to use visual and tactile clues for learning language. 8) Proper articulation of vowels and consonant sound in syllables, words and sentence level. 9) Spontaneous use of language at phonetic level. 10) Satisfactory use of language for effective communication.

1.5.3: Requirements Amplification devices: Children must be fitted with individual amplification devices whether hearing aids or cochlear implant based on their degree of hearing loss. Children with their residual hearing and amplification devices will be benefitted from early chances to listen. Using these devices children hear sounds louder and clearer. Parents need to make decision, what kind of hearing aid to select, and whether or not to consider a cochlear implant. Using of ear mould with the amplification devices is mandatory. Appropriate listening situation: Individual speech and language therapy program should have a good listening environment for the hearing impaired children. If possible the room can be made acoustically appropriate for the hearing impaired children where therapy program can be done. Training materials: Training materials include toys and books, tools for auditory training such as different noise makers and instruments generate different frequency tone. Audio-visual aids like multimedia projector, ; elaborate outdoor play equipment that facilitate therapeutic and academic training.

1.5.4: Plan of action In the recent times, there has been increasing support of intervention occurring within the child's and family's functional and meaningful routines and experiences dispersed throughout the day rather than in tightly planned and executed activities. This shift away from traditional, clinical models for services for young children and their families is aligned with the federal mandate to provide services in natural environments and is responsive to the success of parent-implemented interventions. The use of routines and everyday activities as a context for embedded instruction involves (a) identifying the sources of learning opportunities occurring regularly in family and community life; (b) selecting, with the parents and caregivers, desired participation and desired communication by the child in the routines; (c) mapping motivating aspects and the child's interests within the routines; and (d) identifying facilitative techniques that will be used to maximize the learning opportunity. Organization of the ever-expanding research base on effective intervention approaches and strategies in early intervention is challenging for a variety of reasons. The focus of intervention may be the parent or caregiver, the child, the dyadic interaction, the environment, or combinations of these factors. The agent of the intervention may be the SLP, another team member, a family member or peer, or varying combinations. The intervention may be in small or large groups, individual or massed, or distributed opportunities throughout the day. Much of the empirical data collected to date have been on preschoolers rather than infants and toddlers, and the quality and preponderance of the evidence are lacking for some intervention practices. However, there are intervention approaches and strategies for the SLP and team to consider that have some evidence to support their use by professionals and parents in both home and community settings for young children with a variety of disabilities.

Goals of Early Intervention Receptive language Expressive language Auditory perception Speech development

26 Strategies with promising evidence fall into one of three groups: responsive interaction, directive interaction, and blended. Responsive approaches include following the child's lead, responding to the child's verbal and nonverbal initiations with natural consequences, providing meaningful feedback, and expanding the child's utterances with models slightly in advance of the child's current ability within typical and developmentally appropriate routines and activities. Responsive interaction approaches derive from observational learning theory and typically include models of the target communication behavior without an obligation for the child to respond. Among others, specific techniques include expansions, extensions, recasts, self-talk, parallel talk, and build-ups and breakdowns. Directive interaction strategies include a compendium of teaching strategies that include behavioral principles and the systematic use of logically occurring antecedents and consequences within the teaching paradigm. Blended approaches, subsumed under the rubric of naturalistic, contemporary behavioral, blended, combination, or hybrid intervention approaches, have evolved from the observation that didactic strategies, while effective in developing new behaviors in structured settings, frequently fail to generalize to more functional and interactive environments. The emphasis on teaching in natural environments using strategies derived from basic behavioral teaching procedures has been broadened to include strategies for modeling language and responding to children's communication that derive from a social interactionist perspective rooted in studies of mother-child interaction. The core instructional strategies are often identical to those used in direct teaching (e.g., prompting, reinforcement, time delay, shaping, fading) but also may include strategies that come from a social interactionist perspective (e.g., modeling without prompting imitation, expansions, recasts, responsive communication). Naturalistic language interventions may be used as the primary intervention, as an adjunct to direct teaching, or as a generalization promotion strategy. Monitoring intervention. Because young children often change very rapidly, and families respond differently to their children at various periods in development, systematic plans for periodic assessment of progress are needed. The three broad purposes of monitoring are to (a) validate the conclusions from the initial evaluation/assessment, (b) develop a record of progress over time, and (c) determine whether and how to modify or revise intervention plans. Thus, the evaluation/assessment and intervention processes can be viewed as a continuous cycle of service delivery. Monitoring includes attention to both the child's IFSP as well as broader aspects of the child's development and behaviors, such as

27 participation in routines, play, social interactions, and problem behaviors, to determine appropriate goals in these areas. For children in early care and education programs, attending to their levels of engagement in activities can help determine whether changes are needed in their classroom environment.

1.6: Impact of early intervention on school outcomes.

1.6.1 Schooling Outcomes

Children with hearing impairments are at risk for serious difficulties acquiring and developing literacy skills. Among children with severe to profound hearing impairment, low literacy rates have frequently been reported in the literature. Numerous studies with children who are deaf show that literacy development and proficiency has been challenging for this population (Spencer et al., 2003). Literacy difficulties can impact the child's academic, social and emotional success. When hearing children learn to read, most are competent language users and map their existing phonological, syntactic, semantic and discourse skills onto the newly acquired task of reading. The deaf child approaches the reading task with an incomplete spoken language system and, because reading is a speech based system, this significantly increases the difficulty of the task. As a result, this may facilitate and improve development of speech perception skills in children with hearing impairment (Watson, 2002).

1.6.2 Academic problems faced during classroom situations

Unmanaged hearing loss can result in lagging behind at least 1 grade level. If untreated by 4th grade these students are at least 2 grades below level. Compared to peers with normal hearing-10xs greater risk for academic failure. Cannot "overhear" others' conversations therefore misses passive learning opportunities. Cannot hear soft/distant voice and described as "daydreaming" or "not trying" 50-75% of information missed in classroom situations. Articulation and syntax deficits as well as limited receptive and expressive. Distinguishing and understanding speech in classroom environment (even when

28 presented in the "good ear") Distinguishing soft/distant speech Responding to subtle cues in conversation Rapid-paced information/transitions Distinguishing grammatical markers (possessive, plural, verb tense forms, etc.) Localizing source of sound and filtering speech in noise Not as confident and more dependent on others as compared to peers with normal hearing. 1.6.3 Early stimulation, at preschool age Schooling outcomes, which range from the number of years completed to academic performance, were some of the most widely studied in the evaluations of interventions from early childhood on later outcomes. There are a number of possible pathways through which early childhood interventions could affect schooling. For instance, improved cognitive development could result in increased scholastic achievement, while healthier children are better able to attend classes. A 2003 systematic review of the effectiveness of comprehensive early childhood development (ECD) programs in the United States revealed significant improvements in school readiness, achievement, and retention rates among enrolled children (Anderson and others 2003). Additional long-term studies demonstrated that children who attend these programs were less likely to repeat a grade and more likely to graduate high school when compared with their peers who had not been enrolled (Schweinhart 2007). Two decades after children participated in Chicago's Child-Parent Centers, they demonstrated lower rates of grade retention, a lower likelihood of being enrolled in special education programs, and a higher percentage of high school completion (Reynolds and others 2001). At age 28, their schooling achievements translated to labor market gains and reduced arrest rates. Evidence exists that early childhood interventions can successfully promote on-time enrollment. The most widely studied educational outcome was years of schooling completed, and the evidences suggest that over time, various intervention types could positively affect this indicator. Attendance and completed schooling are important measures, but they do not necessarily indicate if students are learning. children with early intervention are more likely to be in mainstream education, including a special unit within the school (75 to 95 per cent), than in a school for the deaf (five to 21 per

29 cent); second, children with early intervention are less likely to be in schools for the deaf (five to 21 per cent) than profoundly deaf children without early intervention (29 to 46 per cent). Over half of the children in the early intervention group scores within the average range for their age, when compared with hearing children. Factors such as higher nonverbal intelligence, higher socio-economic status, female gender and onset of deafness (later as opposed to earlier) were all associated with reading competence. In children with normal hearing, language skills and literacy are highly interdependent and progressively develop throughout the elementary school years (Watson, 2002). During the initial stages of reading (from birth to six or seven years of age), the child develops the knowledge that words are made up of individual sounds and there is a relationship between each letter and its' sounds (Spencer et al., 2003). During the later stages of reading (from seven years of age to approximately fourteen years of age), the literacy demands increase. Children are expected to develop both "top down" (i.e., meaning to print) and "bottom up" (i.e., print to meaning) processing skills to aid in comprehension (Spencer et al., 2003). It is hypothesized that early intervention provides the child with the ability to utilize phonological ("bottom up") strategies therefore allowing them to decode unfamiliar words. Stimulation, whether through home visits or preschool, can positively affect children's academic performance. Evidence suggests that the persistence of effects over time varies by outcome domain, and longer exposure to some programs can be beneficial. 1.7 Intervention of late identified children with hearing loss A hearing loss in a child, regardless of type, can lead to a variety of consequences like significant delay in language development or disorder in speech perception and production or an interference with both receptive and expressive language. Other effects include effects on cognition, educational attainment, social development and family child interaction. 1.7.1 Challenges of Intervention: The first premise is that it makes sense to

begin intervention with children who have hearing loss when they are very young

because of the research on particular sensitivity of the brain's neural pathways to auditory input prior to the age 3 (Sharma et al., 2005) as well as because of the verbal and academic deficits often seen in

30 children whose audiological and educational management begin later (Geers & Moog, 1989; Nicholas & Geers, 2006). The second premise is that it makes sense to help these children learn to listen and talk in order to keep as much as the world open and available to them as possible. The third premise is that it makes the most sense to help the parent help the child learn spoken language through listening.

The idea is to maximize the child's development through optimizing the family's capacity to address the child's needs.

Working in partnership should result in the most effective intervention with very young children (Bromwich, 1981; Yoder & Warren, 1998, 2002). The fourth premise is that in

acquiring spoken language through listening, a child with a hearing loss will generally follow a normal developmental path.

The pace may be somewhat slower, and there may be some asynchronies in learning related to difficulty in hearing particular aspects of language (Estabrooks, 2006; Tye- Murray, 2003). 1.7.2 Habilitation Strategies: Often with children, aural rehabilitation services would more appropriately be called habilitative rather than rehabilitative. Rehabilitation focuses on restoring a skill that is lost. In children, the skill may not be there in the first place, so it has to be taught- hence, the services are habilitative, not rehabilitative. Specific services for children depend on individual needs as dictated by the following: The current age of the child The age that the hearing loss started The age at which the hearing loss was discovered The severity of the hearing loss The type of hearing loss The level of hearing loss The age at which hearing aids or assistive devices were introduced The aural habilitation plan is also influenced by the communication methods the child is using. Examples of communication methods include the following:

31 Auditory-oral American Sign Language Total communication Cued speech Manually coded English One of the most serious concerns of a hearing loss beginning in childhood is its disruption to learning speech and language.

The combination of early detection and early use of amplification has been shown to have a dramatically positive effect on the early language abilities of children with a hearing loss. In fact, infants identified with a hearing loss by age 6 months can be expected to reach language development similar to hearing friends. Aural habilitation/rehabilitation services for children typically involve the following: Training in auditory perception. This includes activities to increase awareness of sound, identify sounds, tell the difference between sounds (sound discrimination), and attach meaning to sounds. In the end, this training increases the child's ability to tell one word apart from another using any remaining hearing. Auditory perception also includes developing skills in hearing with hearing aids and assistive listening devices, and learning how to handle easy and difficult listening situations. Using visual cues. This goes beyond separating sounds and words on the lips. It involves using all kinds of visual cues that give meaning to a message, such as the speaker's facial expression, body language, and the context and environment in which the communication is taking place Improving speech. This involves skill development in the production of speech sounds (by themselves, in words, and in conversation), voice quality, speaking rate, breath control, loudness, and speech rhythms. Developing language. This involves developing language understanding (reception) and language usage (expression) according to developmental expectations. It is a

complex process involving concepts, vocabulary, word knowledge, use in different social situations, narrative skills, expression through writing, and understanding rules of grammar

Managing communication. This

involves the child's understanding the hearing loss,

32 developing assertiveness skills to use in different listening situations, handling communication breakdowns, and modifying situations to make communication easier.

Managing hearing aids and assistive listening devices. Because children are fitted with hearing aids at a young age, early care and adjustment are done by family members and/or caregivers. It is important for children to participate in hearing aid care and management as much as possible. As they grow and develop, the goal is for them to do their own adjustment, cleaning, and troubleshooting of the hearing aid and, ultimately, to take over responsibility for making appointments with service providers. CARHART (1947) Includes both childhood and adulthood procedures. It has 4 stages. It is based on the belief that since listening skills is normally learned early in life, the child possessing a serious hearing loss

at birth or soon after will not move through the normal developmental stages important in acquiring these skills.

Development

of awareness of sound The child has to recognize when a sound is present and attend to it. The child should be surrounded with sounds that are related to daily activities and that are clearly audible. Development of gross discrimination Initially involves demonstrating with various noisemakers that sounds differ. Training at this level involves discrimination of several parameters of sound, such as intensity (loud versus soft) duration (long versus low)

Development of broad discrimination among simple speech patterns By now the child is aware that the sound differs and is ready to apply this knowledge to the understanding of speech. Familiar meaningful phrases that is sufficiently different to minimize confusion. Development of finer discrimination for speech. Fine discriminations of speech stimuli in connected discourse and integrating an increased vocabulary to enable him or her to follow connected speech in a more rapid and accurate fashion.

33 Carhart also felt that the use of vision by the child should be encouraged in most auditory training activities. 1.7.3

Traditional approach: Hirsh 66, Ling 76, has described 4 levels of audition that contribute to the perception of conversational speech, detection, discrimination, identification and comprehension. Detection requires only the child should be able to distinguish between the presence and absence of sound. Discrimination: involves differentiation of speech sounds. Identification: requires the child to recognize the speech signal and to be able to identify.

Comprehension: involves understanding of the message on a cognitive and linguistic basis. Erber and Hirsh 78 suggested an auditory training program in which increasingly complex speech stimuli are presented for processing through 4 levels of audition.

Speech Syllables Words Phrases Sentences Connected discourse Detection(+/-) Discrimination (same/diff) Recognition(identification) Comprehension(understanding)

The first 2 stages are not usually done. The suprasegmental part is not included here; it taps only long term memory.

Mastery of the lower levels of detection and discrimination is considered to be the pre requisite for successful performance at the higher level of identification and comprehension. Children should progress through the four levels and the various stimulus complexities at their own rate and to the extent dictated by the status of their residual hearing. The detection level in the matrix does not correspond to the awareness stage as proposed by Carhart, because it focuses on speech reception rather than awareness of the sounds in general.

In addition, there is no corollary in the Erber and Hirsh paradigm for the development of gross discriminations of non speech sounds as proposed by Carhart.

34

Acoupedics: The term coined by Dr. Henk. Developed by Pollack (1964)

Principle: Early training using audition only, avoidance of lip reading and other cues, and use of normal speech pattern.

Pollack

proposed a unisensory approach toward education and habilitation of hearing impaired children. Pollack's procedures exclude the use of all visual cues, such as speech reading during early training. She emphasizes only on audition and said that audition gets hampered when attention is divided between two or more sensory inputs. The acoupedic approach is also called as the unisensory approach and its recommendations are: - Hearing impairment should be detected early in life. No age is suggested. - Binaural hearing aids should be selected as soon as the hearing impairment is diagnosed. - The child must be given the fullest opportunity to use his residual hearing; hence visual stimuli are not provided initially in other words, lip reading cues available to the child are kept minimal. This does not mean that the child never has the opportunity to see the speakers face. It means that no formal lip reading instruction is employed and the child is expected to develop his auditory capacity in preference to his visual skills in developing speech and language. - Normal patterns of language are stimulated through the visual auditory channel eliminating the need to present language visually. - A favorable attitude must be established for auditory learning. In short, the people who are involved must believe that the child can hear and learn to communicate normally. - Parents must become the primary teachers, assuming responsibility for providing intensive auditory stimulation more or less continuously. - A special educational environment must be avoided. The goal is for the child to be educated with normally hearing children. The following are the listening skills to be worked on: - Awareness of sounds, loud then quiet sounds. - Attending to sounds, increasing the range

35 - Responds to sounds. - Localizing to sounds. - Discrimination of sounds. - Developing auditory feedback mechanism. She emphasized on the development of language through the auditory feedback loop, which is demonstrated and referred by repeated imitation of auditory stimuli. Pollack does not suggest an age but says introduction of the acoupedic approach beyond 7yrs of age may not be feasible, but the procedures are designed for infants and toddlers. 1.7.4 Wedenberys

Approach (Wedenbery 1951): It is an early approach to auditory training, used with children with severe to profound hearing loss. It was first described by Wedenbery. His training also served to exploit whatever residual hearing a child possesses. His approach was eventually labeled as unisensory, since he advocated that speech reading should not be consciously emphasized until the child developed a proper listening attitude. His program was directed towards increasing the Child's attention to the sound. Both environmental and speech sounds were used in the early stages, which he referred to as "ad concham amplification". This involved speaking directly into the Child's ear at a close range (1/2 inches) rather than having the child use hearing aids. Exercises, which helped the child become aware of and attend to sound at increasing distances, were used. These included presentation in isolation vowels & voiced consonants whose formants were thought to be within the hearing impaired Child's audible range. Syllables were used in a variety of formal therapeutic activities, as well as informal settings at home. Combining individual vowels and consonants learned in isolation resulted in perception of a limited number of words. At this point Wedenbery advocates part time use of hearing aid. Later, training progresses to short sentences formed by words already recognized by the child acoustically. Although not given direct focus, speech reading could be used as a supplement. His method directed towards development of auditory, speech and language skills in children with either a congenital or prelinguistic hearing loss. Of severe to profound proportion.

Similar auditory training methods were proposed by Goldstein 39, Watson 61, and Whitehurst 66.

36 Verbotonal: Peter Guberina 1952 It is

effective for establishing good spoken language and listening skills. Based on a developmental model of normal hearing children

Guberina's concept is based on that low frequency of spoken language don't mask high spoken frequencies.

He believes that amplification of auditory cues below 500 Hz to include rhythmic patterns and sound fundamentals can help HI to perceive higher speech frequencies. 1.7.5

Ling's approach: Training programme is based on: - Acoustic characteristic of speech - Emphasis on listening aided by amplification - Involves segments as well as supra segmental - Recognizes need to attain vocal system, respiration, motor control and coordination. Prior to use of speech in meaningful contexts. Ling emphasized that speech should be taught at phonetic level rather than phonological level. Child's ability to detect all six sounds demonstrates that ability to detect all aspects of speech.

Auditory Verbal Practice The goal of Auditory Verbal Practice is that children who are deaf or hard of hearing can grow up in regular learning and living

environment enabling them to become independent, participating and contributing citizens in mainstream society.

Principles: Auditory verbal practice (Pollack, 1970, 1985, 1997) have been incorporated by AV I.

To detect hearing impairment as early as possible through screening programs, ideally in the new born nursery and throughout childhood. -

Prompt detection is critical in that any auditory deprivation can lead to delay in language development. - Lowered the age of candidacy for CI. 1) To pursue prompt and vigorous medical and audiologic management, including

37 selection, modification, and maintenance of appropriate hearing aids, a cochlear implant or other sensory aids. - Appropriate well defined hearing technology in conjunction with AVT can lead to the development of spoken communication. 2)

To guide, counsel, and support

parents and caregivers as the primary models for spoken language development and

to help them understand the impact of deafness and impaired hearing on entire family. 3) To help children integrate listening

in to

their development of communication and social skills. 4) To support children's auditory verbal development through one to

one teaching. 5) To help children monitor their own voices and the voice of other in order to enhance the intelligibility of their spoken language. 6) To use developmental patterns of listening, language, speech, cognition to stimulate natural communication. 7) To continuously assess and evaluate children's development

in above areas

and through diagnostic intervention, modify the program when needed. 8) To provide support services to facilitate children's educational and social inclusion in regular education classes.

The listening environment: AVP encourages the maximum of hearing in order to learn language and stresses listening rather than watching. Listening environment can be enhanced by following conditions. - Parents / therapist sitting beside child, on the side of better ear - Speaking close to child's hearing and / or CI microphone - Speaking in quiet voice at regular volume - Minimizing background noise - Using speech that is repetitive and rich in melody, expression and rhythm. - Using acoustic highlighting technique to enhance the audibility of spoken language.

38 (Auditory Verbal Techniques) includes - Education - Guidance - Advocacy - Family support - It is a part of ongoing, individual, diagnostic evaluation of child's and parent's progress. - Sessions are generating conducted jointly by AVT therapist and parents. - Child learns to listen to his or her own voice. The voices of others and sounds of environment in order to communicate effectively and naturally through spoken language. - Most AVT offers weekly therapy session, lasting for 1 to 1.5 hours. - Mere therapy may or may not be advantageous and depends on many variables. - It is parents / care givers who need to apply targets from each session in natural language contents throughout the day. - Auditory verbal therapist demonstrates parent and the child practice and interaction are discussed. - Auditory verbal therapist outlines specific goals to work towards at home and suggests ways through which they may be achieved. Auditory Verbal Techniques 1) Using acoustic highlighting 2) Using auditory closure 3) Recording 4) Asking "what did you hear?" 5) Providing alternatives 6) Pausing 7) Repeating a previous strategy 8) Waiting

39 9) Rephrasing 10) Labeling by category 11) Asking for providing a definition 12) Changing the task from open set to closed set 13) Providing rhyming words 14) Suggesting opposites 15) Providing a visual clue and putting the stimulus back into hearing 16) Moving closer to the child 17) Directing the child to listen closely 18) Repeating part of the story message containing the answer 19) Using the often misunderstood technique and hand cue 1.7.6 Ski-Hi Approach Clark & Walkins (1985) - Which is a comprehensive identification and home intervention treatment plan for HI infants and children. - This program explains all auditory skills in four phases. - As skill level changes, auditory behavior becomes more complex. Phase I: 4-7 months - Attending - Early vocalization Phase II: 5-16 months - Recognizing - Locating - Vocalizing with inflection Phase III: 9-14 months - Hearing at distance and levels

40 - Producing some vowel and consonants Phase IV: 12-18 months - Environmental sound discrimination and comprehension - Vocal discrimination - Speech discrimination - Speech initiation and uses speech meaningfully Developmental approach to successful listening II (DASL- II): This approach is highly structured and used with preschool and school age children using hearing aids or cochlear implant. The hierarchy used in this approach is: Sound awareness: includes detection, discrimination of both environmental and speech sounds. Phonetic listening: the fundamental aspects of speech perception like duration, intensity pitch and rate are emphasized. In this stage development of discrimination and identification of vowels and consonants in isolation and inwards are kept in mind while planning the activities. Auditory comprehension: comprehension of complex verbal messages in everyday settings is considered. Other communication strategies:

Sign Language: Signs in ASL are created using handshapes, facial expressions, body posture and movement. Some examples are:

o

Handshape - a spread-out hand, as in a "high-five" or a pointing handshape o Fist movement - how you move your hands in space, such as from left to right or in a circling or a bouncing motion, o Facial expression - raised eyebrows when asking a question and smiling when signing about something that is fun to do. Visual Attention: People with hearing can hear voices even when they cannot see who is talking. People who communicate in ASL need to look at the person who is signing to them. It is important to make sure your child is looking and paying attention when you are signing.

41

Eye contact: Eye contact is very important when you are signing in ASL. If you have eye contact with your child, then you can be sure that you are paying attention to each other. Fingerspelling: Fingerspelling began as a part of ASL. Fingerspelling spells words by forming each letter using the hands and fingers. Very young children do not need to know how a word is spelled to understand fingerspelling. Instead they learn fingerspelled words by the shape and movement of the hand. Spoken English Spoken words: Spoken words are formed using the vocal cords (voice) and mouth and are made of speech sounds such as vowel and consonant sounds. Auditory training and listening: Auditory training teaches a child or an adult to rely on listening to communicate. It takes advantage of a person's residual hearing. That is the amount of hearing that a person with a hearing loss still has, even if it is very minimal. Many children who are deaf have some residual hearing. Speech: Speech uses the mouth, lips, tongue, and vocal cords to produce sounds for communication. Speech and auditory training (or listening) are often used together. Different speech sounds can make a difference in the meaning between two words. For example, the only difference between the two words "big" and "pig" is in the first speech sound ("b?" rather than "p?"). Speech reading: In speech reading (also known as "lip reading") a person who is deaf or hard of hearing watches a speaker's mouth and facial expressions to understand what is being said. Speech reading is also used along with other building blocks, such as listening, to communicate. English Coding Systems English coding systems use visual methods to express the spoken English language. Coding systems are not a language of their own. Instead of using speech and hearing, coding uses signs borrowed from ASL to represent the English language. English grammar and word order are used.

Manually Coded English (MCE): Manually Coded English, or MCE, is made up of signs (hand shapes and hand motions) that represent English words. You might have heard of Morse code. Morse code is a system of dots and dashes that can be tapped out to form English words and phrases. MCE is a code for the English language. Many of the signs in MCE are borrowed from ASL. However, the grammar, word order, and sentence structure used in MCE are those 42 of the English language. MCE does not use the grammar, word order, and sentence structure of ASL. Finger spelling: Finger spelling began as part of ASL. Finger spelling is the spelling of words by forming each letter using the hands and fingers. It is used with English coding systems, as well as in ASL. Other communication tools: The remaining three building blocks can be used for communication and language. These three building blocks are cued speech, simultaneous communication, and natural gestures. Cued Speech: Cued speech, or cueing, can help people who are deaf or hard of hearing understand speech. Cued speech is not a language or a representation of a language. Instead, it is a system of hand signals used by the speaker to help the listener tell the difference between certain speech sounds. Some speech sounds are hard to tell apart using speech reading alone. (One example is the difference between the sound of "b" and the sound of "p"). Cued speech consists of eight hand shapes representing consonant sounds. These are placed at four locations near the mouth to represent vowel sounds. Cued speech must be used in combination with speech reading. Conceptually Accurate Signed English (CASE): Conceptually Accurate Signed English, or CASE, is sometimes used by people who are deaf or hard of hearing to communicate with one another. Sometimes it is called PSE, or Pidgin Sign English. CASE is a mix of English and ASL. CASE is not a language. It is a form of communication that varies depending on the experience and preferences of the people using it. Simultaneous Communication: Simultaneous communication is a technique that can be used with MCE. The person signing speaks and signs at the same time. The person listening and watching uses speech reading, hearing, and MCE or CASE to understand what is being said. Natural gestures: Natural gestures are body movements and facial expressions that you often use to help others understand your message. For instance, if you want to hold a child, you can simply stretch your arms towards the child. Or, when you put your index finger over your mouth and nose you are telling someone to be quiet. These are examples of natural gestures.

43 1.8

Let Us Sum Up Regardless of culture, children around the world with untreated hearing loss tend to experience: problems with speech development, language, and communication skills (especially if severe hearing loss occurs at birth or before speech and language is acquired) emotional difficulties and low self-esteem learning and behaviour problems in school Children, who have their hearing loss treated, enjoy many life benefits including: closer relationships with their family and friends better feelings about themselves and higher self-esteem improved mental health, greater self-confidence, independence, and security learning skills equal to children with normal hearing Having a hearing loss brings with it many characteristics that affect the learning of the student. However, the hearing loss alone is not necessarily accompanied by such characteristics as visual-perceptual problems, attention deficits, perceptual-motor difficulties, severe inability to learn vocabulary and English structures, consistent retention and memory problems or consistent distractive behaviors or emotional factors. If any of these kinds of behaviors characterize the student who is deaf or hard of hearing, then an investigation into the possible influencing factors should be requested.

There are many terms used to refer to bring about these skills in the child with hearing impairment. Among these, Audiologic habilitation, (ASHA, 1974), Rehabilitative audiology (Dyer & Frankmann, 1975) and Aural Rehabilitation (Ross, 1972, O'Neill & Dyer, 1973, Schow & Nerbonne 1980; Sanders 1982) are common. Audiologic habilitation or rehabilitation is defined as such professional efforts that are designed to help a person with hearing loss. These include services and procedures for lessening or compensating for

a hearing impairment involving facilitation of adequate receptive and expressive communication (ASHA 1984 & ASHA 1982). There is a distinction between 'habilitation' and 'Rehabilitation'. 'Habilitative' treatment is applied when early onset of hearing impairment has prevented the initial development of language and other communication skills (Prelingual hearing impairment). 'Rehabilitative' treatment focuses on the restoration, the maintenance and in some cases the expansion of communication skills developed prior to the onset of hearing impairment (i.e. post lingual hearing impairment). The main objective of this process involves assisting the persons with hearing impairment to attain full potential by using personal resources to overcome difficulties resulting from the hearing loss. There are other closely related important services for the persons with hearing impairment but distinct from audiologic habilitation or rehabilitation process. These are Medical intervention and Education of the children with hearing impairment. After thorough audiological evaluation and completion of medical treatment, aural rehabilitation is generally started. Education of the children with hearing impairment generally begins and simultaneously continues with the rehabilitation process. Management of these conditions is dependent on the individual needs of each child with hearing impairment and these include:

47 1. Hearing aid selection and fitting. 2. Auditory training. 3. Speech and language stimulation. 4. Speech reading training. 5. Enrollment in proper educational setting. A child with hearing impairment should depend upon his or her residual hearing and need to develop his auditory listening capacity to acquire verbal language skills. There is a well established relationship among hearing or auditory listening ability, language acquisition and speech development. For development of speech and language or verbal communication skills one has to depend on his auditory listening capacity. Such kind of rehabilitative management is guided by the professionals working as a Team. The Team: In audiologic rehabilitation process all aspects of the management are not performed by one person. In fact, professionals from several different disciplines are often involved, including Special educator, Psychologist, speech language Pathologist, social workers and rehabilitation counsellors. Nevertheless, the Audiologist is often considered the major provider of such services with specific goals as needed by the child with hearing impairment. Goal: Although primary and secondary prevention of the hearing loss can be initiated through different awareness and immunization programme and proper medical treatment, the major goal of aural rehabilitation is the improvement of communicative abilities in the persons with hearing impairment. Early identification, proper audiologic evaluation and management are essential to the remediation of hearing handicappedness which is dependent upon some factors. Factors: The important factors relating to audiologic rehabilitation include: 1. Degree of Hearing impairment. 2. Time of Onset. 3. Type of loss. 4. Auditory Speech recognition abilities.

48 5. Parental involvement. 1. Degree of Hearing loss: The prime factors for aural rehabilitation are the person's loss of hearing sensitivity or degree of hearing loss (vide table 1). Depending on the residual hearing along with the other factors the communication options can be selected. Classification Hearing level (dB) 1.

Normal hearing sensitivity 0-25 dBHL 2.

Mild Hearing loss 26 - 40 dBHL 3. Moderate Hearing loss 41 - 55 dBHL 4. Moderately severe Hearing loss 56 - 70 dBHL 5. Severe hearing loss 71 - 90 dBHL 6. Profound hearing loss 91

dBHL or more. Table 1. Classification of Hearing Sensitivity; Goodman 1965 However, the category of hearing impairment can be broadly classified into two types: i) Deaf and ii) Hard of hearing. The term Deaf is used to denote any person whose auditory channel is sufficiently damaged to preclude the auditory development and comprehension of speech and language with or without amplification (Ross 1977). Generally, when hearing loss measured by pure tone average (PTA) and speech recognition threshold (SRT) are poorer than 80 to 90 dBHL, a person is considered to be audiometric deaf (Schow 1989). Hard of Hearing : Hard of hearing child is such child with hearing loss who is more like the normally hearing child and primarily uses the auditory channel for speech and language and social development. They can be divided into two groups: i) Hard of hearing I (HOH-I): These children with hearing loss of mild to severe degree uses their hearing aid in their daily routine and academic vocabulary fair to excellent. They sometimes use full sentence and their parents are involved with them. ii) Hard of hearing II (HOH-II): These children with hearing loss are of mild to moderate degree and they never use amplification by any means. Their parents

49 are unaware about it. Their language is usable but immature. They are easily getting bored, inattentive and frustrated.

2. Time of onset: According to the onset of Hearing loss there are two categories of deaf persons: i) Pre-lingually Deaf: These persons were either born without hearing (congenitally deaf) or lost hearing before the development of speech and language i.e. 3-5 years of age. ii) Post-lingually Deaf: These persons were those who became profoundly deaf after the age of 5 - 10 years i.e. the development of speech and language.

3. Type of Loss: Hearing impairment can be of five types: such as i)

Conductive hearing loss: damage in the outer and middle ear. ii) Sensorineural hearing loss: impairment in the inner ear and nerve of hearing. iii) Mixed hearing loss : Combination of conductive and sensorineural. iv) Central auditory processing disorder (CAPD): v) Functional hearing loss (nonorganic) or Pseudohypacusis. Generally conductive hearing losses are treated with medical intervention whereas sensorineural hearing losses are primarily aided through audiologic rehabilitation. In case of sensorineural losses auditory speech recognition or hearing clarity is usually affected. This is also the case in difficult listening situations for those with central auditory processing problems.

4. Auditory Speech Recognition Abilities: The terms speech detection, speech discrimination or word discrimination, Speech recognition or identification and speech intelligibility are used with signal as the stimulus. It is the major goal to communicate with verbal language. The speech recognition ability in an individual who is hard of hearing typically is better than a person who is Deaf. Person who are deaf are generally considered unable to comprehend conversational speech with hearing alone whereas those who are hard of hearing can use their hearing to a significant extent for speech perception. But Ramsdell (1978) pointed out that however some minimal auditory recognition may be present in a person who are deaf even if verbal speech reception is limited; since a person may use hearing for alarming purposes or simply to maintain communication with the auditory environment. Nevertheless, auditory recognition ability and degree of hearing loss are somewhat independent.

50 In adult person, a mild degree of loss sometimes may be accompanied by very poor speech recognition. This is referred to as phonemic regression and is not usual in hearing losses among elderly persons who show some degree of central degeneration. Disparity in degree of loss and speech recognition ability is also possible in young persons with hearing impairment. For example, a child may be considered deaf in terms of sensitivity but not in terms of auditory recognition or educational placement. Some children with a degree of loss that classifies them as audiometrically deaf (PTA = 90+ dB) may have unexpectedly good speech recognition. Thus speech recognition also is an important variable in describing hearing loss.

5. Parental Involvement: The parents of the child with hearing impairment should understand the needs of the child and provide a normal happy environment in which they enjoy the activities and experiences of the hearing child. The needs for these children with hearing impairment are: i) Regular use of the hearing aid and importance of improving listening. ii) Effective speech and language stimulation. iii) Training of the other senses like vision and tactile to aid learning. Parents should help the child with hearing impairment to accept the hearing aid and taking care of it in terms of checking and maintenance. They can provide Role model to the child for speech and language stimulation and create an optimal listening environment and carrying out activities at home that will facilitate good listening habits. All the daily events which create sounds can be converted into listening activities. Parents provide the child various opportunities for language stimulation and make every daily routine activity into an interesting language learning experiences. Parents must speak to their child naturally and clearly. They can create every opportunity to present meaningful language to the child. Mother can talk on behalf of the child as well as herself. They can play, sing and dance with the child and encourage the child to talk and explain when he attempts to express himself. They can involve other siblings in various activities and play with noise making toys. Parents can give children opportunities for sorting, making various objects, feeling the objects and guessing them. These activities also provide ample opportunities to the child with hearing impairment to learn language auditorily for mainstreaming.

51 2.2 Objectives The primary objectives of Auditory Learning is - 1. to use their even minimal amounts of amplified residual hearing. 2. to listen to speech and learn to speak using their amplified residual hearing. 3. to grow up in regular learning and living environment through developing the ability to listen to and to use communication with their family and mainstream community. 4. to develop personality and emotional adjustment. 5. to open up vocational opportunity.

2.3 Concept of Auditory Listening: Unisensory and Multisensory approaches: 2.3.1 Human communication System: In prehistoric period human being used to vocalize or signing with his fingers or made marks on sand or caves to share their thoughts with others. With the evolution of the auditory system human being developed and refined their communication system. The structure of language is unique to the human beings although researchers have demonstrated that signed symbols and other visuals language forms can be taught to chimpanzees and believe that the beginnings of true language are evidence in these primates (Gardner and Garner, 1969; Premack and Premack, 1972; Savage- Rumbaugh et. al. 1980). Today we possess the most advanced communication system among all creatures of the universe because

we have developed the auditory system and vocal mechanism through which language is customarily learned and communicated.

The interdependence of the ear and speech is found in the direct relationship between the frequencies that make speech intelligible and differential sensitivity of the human ear which is most sensitive precisely at the frequencies of speech. The human baby appears to be born with "preexistent knowledge" of language - specialized neural structures in the brain that await auditory experience with language to trigger them into functioning. These structures which are termed as Language acquisition device (Chomsky, 1966) which is dependent on auditory stimulation for

52 their emergence provided all other factors are normal. The auditory linked acquisition of language is further unique to human beings because it is a time locked function related to early maturational periods in the child's life. The longer the auditory language stimulation is delayed, the less efficient will be the language

facility. The reason is that critical periods exist for the development of biologic functions and language is one of the biologic functions of humans (Chomsky 1966, Lenneberg 1967). If a child is deprived of language stimulation in his critical age period they will never attain his or her best potential language function due to hearing impairment or lack of language experience. Therefore, it is urgent to prevent the hearing problems of children with all skills and knowledge.

The prevention of hearing loss in children protects the right of children to their essential humanity which lies in optimal language function. 2.3.2 Communication Model: Generally the ability to communicate meaningfully has been considered a prime factor in differentiating humans from other forms of life. Human communication can take a variety of forms, involving the conveyance of various stimuli to one or more of our sensory modalities. The form of communication most often used to express oneself, oral communication, involves utilization of speech. This creates an extraordinary dependence on the sense of hearing in order to receive and perceive adequately the complex network of auditory stimuli which comprise speech. The sense of hearing, therefore, is crucial to the process of verbal communication. Most of the time we are dependent on our ability to receive and interpret auditory stimuli presented during oral communication, though a portion of the communication that normally takes place between individuals is nonverbal as gestures, sign, facial expression etc. Successful oral communication involves a number of key components that originate with a source or speaker who has both a purpose for communication and the ability to properly encode an articulate the thought to be conveyed. The actual thought to be expressed is termed as message which is made up of auditory stimuli organized in meaningful linguistic units. Visual cues are also provided by the speaker in conjunction with the production of the auditory message. An important component of the encoding process is the feedback mechanism, made up primarily of the auditory system of the speaker, which makes it possible to monitor and if need be, correct the accuracy of the intended message. The communication situation in which the message is conveyed is referred to as the environment. The final major component of the communication process is the receiver or listener who is charged with the responsibility of receiving and properly decoding and interpreting the speaker's intended thought.

53 The basic components of the oral communication process and their sequence are found in figure 1. All the major components are equally important in accomplishing the desired end- communication. Disruption or elimination of any one part may result in partial or complete failure of the communication process. Feedback Message (Auditory and visual) ENVIRONMENT Figure 1. A simple oral communication model. 2.3.3 Auditory Perception: Unisensory Approach Our ability to communicate verbally with others depends to a great extent on the quality of our auditory perception of the various segmental (individual speech sounds) and suprasegmental (stress, rate, rhythm, intonation) elements that comprise speech. Auditory perception of speech and nonspeech signal involves only one sensory system i.e. Hearing or auditory system. Therefore, it is called as unisensory (uni means single) approach of auditory perception. Perception of Non-speech Stimuli: In terms of signal processing the human auditory system has sophisticated perceptual capabilities though it is limited, to some extent, in terms of the signals it can process. Optimally, the normal human ear is capable of perceiving auditory signals comprising frequencies between about 20Hz and 20000Hz. Stimuli made up entirely of frequencies below and above these limits cannot be detected. Intensity limits vary as a function of the frequency of the auditory signal. The maximum range of intensity we are capable of processing occurs at 3000 - 4000 Hz. and varies from about 0-140 dB SPL. Signals with intensity less than 0 dB SPL are generally not perceived; in contrast, signals in excess of 140 dB SPL produce the sensation of pain rather than of hearing. In addition to the detection of acoustic signals, the human ear is also able to discriminate different stimuli on the basis of only minor differences in their acoustical properties. Source (speaker) Receiver (Listener)

54 Our ability to discriminate differences in auditory signals has based around three parameters of sound; namely, frequency, intensity and duration. Results of such investigations have revealed a complex interaction among these variables. Thus, our ability to discriminate changes in the frequency, intensity or duration of a signal is influenced by the magnitude of each of the other factors. Stevens and Davis (1938) estimated that the normal ear is capable of perceiving approximately 340,000 distinguishable tones within the audible range of hearing. This total number was based only on frequency and intensity variations of the stimuli and it suggests that our auditory system have amazing discrimination powers. Perception or Comprehension of Speech: The organization and production of the segmental and suprasegmental elements of speech into a meaningful oral message by the speaker and the accurate reception of this dynamic signal by the listener represent a highly complex, sophisticated process. However mere reception of the speech stimuli by a listener does not result in proper perception of the message. Speech perception implies understanding and comprehension and the reception of speech signals by the auditory mechanism is only a first step in its perception. In its most basic form, the perception or comprehension of speech may be thought of as involving a number of components. Among these are: DETECTION : This aspect of auditory perception involves experiencing the awareness of sound. Our ability to detect speech is influenced by our hearing acuity and the intensity level of the speech signal. DISCRIMINATION : Speech discrimination refers to the ability to distinguish among the individual speech stimuli (phonemes, syllable etc.) of our language. How accurately we perceive the individual elements of speech is relevance. IDENTIFICATION : The ability to identify or label what one has heard by repeating pointing to or writing a word or sentence. ATTENTION : A fundamental ingredient in the perception of speech relates to attending to or focusing on the speaker and the message being conveyed. The degree and quality of the listener's attention will influence how well speech is perceived. MEMORY : A key component in speech perception is the ability to retain or store verbal information for relatively brief periods or in some instances, extended lengths of time. Memory is also fundamental to other components of speech perception and enables us to combine individual speech units for the purpose of deriving meaning from an entire verbal message, rather than from each individual unit of the message.

55 CLOSURE: The speech elements which are received properly discriminated and retained for further processing must be brought together into a meaningful whole. This is a difficult task at best, but when we do not adequately receive all the contents of verbal message, as often occurs with a hearing loss, closure can still occur through a process when missing information is deduced by the listener on the basis of the available context. SPEECH PERCEPTION AND HEARING LOSS The persons with hearing impairment cannot perceive the speech signal as they are not able to receive and process the coded acoustical information of the speech signal like the person with normal hearing. The effects of different physical properties of speech, redundancy and constraints on speech perception have an effect on their perception of speech. Physical properties of Speech: Speech contains energy from roughly 50 - 10000 Hz and is normally presented at average intensity levels of around 45 dBHL; it is well within the sensitive range of the normal human ear. But person with hearing impairment cannot do so. No longer are the intensity and frequency ranges of the impaired ear always sufficient to provide total perception of the speech signal. One or both of these stimulus parameters may be limited such that it becomes difficult to hear specific speech sounds adequately for identification of speech sounds. For vowel perception, Owens, Benedict and Schubert 1971 studied that most persons with hearing impairment experiences only minimal difficulty. Specifically, they found that the vowel phonemes /e/ and /o/ were found to have the highest probability of error. Only when the degree of impairment is severe to profound does the perception of vowels become significantly altered (Erber, 1979). Consonant perception is more difficult for the person with hearing impairment. Owens (1978) found phonemes such as /s/, /p/, /k/, /d/, and /th/ to be among the most frequently misarticulated by adults with sensorineural hearing loss. He also found that they have more discrimination problem in phonemes in the final position of word than in the initial position. The most common errors in consonantal phonemes discrimination occur with the place of articulation feature (Boothroyd, 1978; Byers 1973, Owens 1978) followed by the manner of articulation. Errors in the perception of nasality and voice among consonants are generally far less frequent.

56 Regarding perception of consonants, Owens et al. (1972) examined the relationship between the configurations of the audiogram and the specific consonant perceptual errors made by a group of persons with hearing impairment. The /s/, /S/, /tS/ /dz/, /t/ and /th/ in the initial position only were found to be difficult for listeners with slopping audiogram configurations. The authors also noted that these phonemes became increasingly difficult to hear accurately as the steepness of the slopping high frequency hearing loss increased. Correct recognition of /s/ and the initial /t/ and /th/ were found to be closely related to hearing sensitivity above 2000Hz whereas perception of /s/, /ts/ and /dz/ was very dependent on sensitivity between 1000Hz and 2000Hz. These findings point out the crucial role of hearing sensitivity in these frequency region plays in the perception of several consonant phonemes. Authors pointed out that these information concerning phoneme errors is useful in establishing audiologic rehabilitation strategies for persons with hearing losses of this type.

Redundancy and Noise: The perception of speech is a highly complex process that involves more than the acoustics of speech or the hearing abilities of the listeners, even though these are important variables. For oral communication to be successful, sufficient information must be present in the message of interest for it to be perceived. The amount of information available for a given communication situation is closely associated with the concepts of redundancy and noise. The degree of redundancy in oral communication varies from one expression to the next, so the extent to which a listener can predict what was said will also vary. Basically, the more redundant a message, the more readily it can be perceived by the listener, especially in difficult listening situations. A number of factors present in a given communication situation can influence the amount of redundancy. Among the many factors associated with the redundancy or predictability found in conversational speech for the listeners to use for perception are structural, semantic and situational constraints. Structural constraints relate to the predictable manner in which linguistic units are chained together according to the rules associated with a particular Language. The selection and use of phonemes and words in an utterance are strongly influenced by these rules, making it easier for the listener to predict what is to follow after having heard only the initial portion of the sentence. Such syntactic clues can be used in conjunction with another factor related to redundancy, namely semantic constraints to be used based on the general semantic content of the expression. When the topic of conversation is food, for example, the listener can expect to hear a rather restricted range of vocabulary peculiar to that particular topic. Use of this small range

57 of words will increase the redundancy in what is said. Situational constraints also create redundancy. Our conversational partner, the location of the conversation, the time of the day it takes place and other similar factors all influence what we say and how we say it, which can make conversational speech somewhat predictable. All of these types of constraints, along with other factors collectively produce the redundancy that makes the perception of speech easier for us all. Noise in oral communication refers to a host of factors that can actually reduce the amount of information present for the listener to use. In this context, "noise" refers to a variety of variables that can be counterproductive to communication, not just competing auditory noise associated with oral communication with which the listener must contend. Each of these factors may reduce the amount of information in a spoken message, thus reducing the amount of redundancy or predictability which is available for the listener to use in perceiving speech. Thus the degree of information available for the listener to use in perceiving a message is influenced in a positive or negative manner by a number of related variables that are part of oral communication. For the listener, particularly one with hearing impairment, the importance of each of these variables to the process of speech perception cannot be overstated.

2.3.4 Visual Stimuli in Communication: During conversation we tend to rely primarily on our hearing to receive and subsequently comprehend the message being conveyed. In addition, given the opportunity, we look at the speaker in order to obtain further information related to the topic of conversation. The speaker's mouth movements, facial expressions and hand gestures as well as various aspects of the physical environment in which the communication takes place, are potential sources of useful information. Humans beings learn to use their vision for communication to some extent, even though most of us enjoy the benefits of normal hearing and find it unnecessary in most situations to depend on vision to communicate effectively. The person with hearing impairment on the other hand is much more dependent on visual cues for communication. The degree to which persons with hearing impairment need visual information when conversing is proportional to the amount of information that is lost due to hearing impairment. In other words, a person with a severe hearing loss is likely to be more dependent on visual information to communicate than an individual with a mild auditory impairment.

58 Visual information may be transmitted by means of a manual or an oral communication system. In oral communication, the listener uses visual cues by observing the speaker's mouth, facial expressions, and hand movements to help perceive what is being said. This process is referred to as many terms, such as lip reading, visual hearing, visual communication, visual listening and Speech reading. These terms seem to imply the use of only visual cues for purpose of identifying various articulatory gestures. However, since the use of vision for communication involves more than watching the speaker's mouth, it is preferably called as Speech Reading which is called by the lay person as Lip reading. When the speech reader uses tactile cues for speech perception by placing the fingers and hand on the speaker's lips, face and neck, it is termed as TADOMA. This method has proven successful with some individuals with both deaf and blindness (Reed, et al., 1985). Manual communication or "Sign Language" also depends on a visual system. Manual communication is transmitted via special signs or a symbol made with the hands and is received visually. This complex form of communication allows for transfer of information via the visual when both the sender and the receiver are familiar with the same system of symbols.

2.3.5 Multisensory Approach of Speech Perception: Apart from hearing sensitivity, some parts of speech can be perceived by other sense organ like vision and tactile. Multisensory means inclusion of more than one sense organ. Therefore the approach which includes other sense organ for perception of speech is termed as Multisensory approach. It can be included in the second major classification of oral methods named as auditory-visual-oral (AVO) methods. In AVO programs emphasis remains on auditory stimulation, with the addition of training in lipreading and presentation of language in print, either through natural approaches or structural approaches. Some individuals categorized Finger spelling under multisensory oral approaches. The use of finger spelling has been incorporated into many different names including Visible speech and Rochester method.

2.4 Auditory Training: Importance, Types and Stages The major component of the audiologic rehabilitation process has been considered as Auditory training which is actually a systematic training of the residual hearing for the improvement of auditory abilities of the person with hearing impairment.

59 Definition:

Numerous attempts have been made to define auditory training in the past.

The most commonly referred to definition of Auditory training is attributed to Carhart (1960).

According to him Auditory training refers to the process in which hearing impaired persons learn to take full advantage of sound clues still available to him. According to McCarthy and Alpiner (1982) Auditory training can be defined in terms of three (3) activities: i) Learning to recognize auditorily those speech sounds which are incorrectly discriminated. ii) Improving adjustment to learning aid fitting. iii) Recommendation for strategies or assistive devices to resolve the client's specific situational communication problem. Erber (1982) described Auditory training

as

the creation of spectral communication conditions in which teachers and audiologist help the children with hearing impairment

acquire many of the auditory perception abilities that normally hearing children acquire naturally without professional intervention. 2.4.1 Importance of Auditory Training;

The primary goal of Auditory training is usually to maximize receptive communication ability by using audition. Achieving this basic goal can result in other important achievements; i. It improves listening skills of the persons with hearing impairment. ii. Learning to maximize the use of auditory and other related clues available for the perception of speech. iii. Adjustment, acceptance and orientation to facilitate the optimum use of amplification such as hearing aids, cochlear implant and tactile devices. iv. It creates better understanding of the spoken language and improves Speech and Language and communication skills with better clarity. v. Increase tolerance for loud speech and environmental sounds. vi. The training creates Educational and vocational advancement vii. Successful psychosocial coupling and orientation to the hearing world. viii. To improve dynamic range of hearing.

60 2.4.2 Different approaches of Auditory training: The earliest efforts in Auditory training date back to the 18th century. Throughout the 1800s, European used auditory training with the persons with hearing impairment and noted success in some cases. Influenced with their achievements Goldstein (1939) introduced the Acoustic method which is centered around systematic stimulation with individual speech sounds, syllables, words and sentences to improve speech perception and to aid deaf persons in their own speech production. Early applications of auditory training were directed almost exclusively toward children with severe to profound hearing loss in a deaf education setting. In recent times, however use of auditory training has been expanded to include those with less severe impairments, as well as the inclusion of auditory training activities in the rehabilitative management of the hard-of-hearing adults and children. With the improvements of hearing aids and cochlear implants, growth in the use of auditory training increased following World War II and the interest shown by Audiologists in maximizing the use of residual hearing in persons with varying degree of hearing loss as a part of the audiologic rehabilitation process. Therefore all approaches can be divided into two categories: I. Traditional Auditory training Methods: Wedenberg Methods: Wedenberg (1951) described a systematic process of auditory training which serves to exploit whatever residual hearing a child possesses. This approach is a unisensory approach as

speech reading does not consciously emphasized until the child developed a proper listening attitude.

The preliminary efforts in this auditory training program were therefore

directed towards increasing the child's attention to both environmental and speech sounds

at an early stage. Wedenberg introduced 'ad concham amplification' - which involves

speaking directly into the child's ear at a close range rather than having the child use

a hearing aid. This type training also included exercises which helped the child with hearing impairment

become aware of and attend to sound at increasing distances. Vowels and voiced consonants whose formants were thought to be within the hearing impaired child's audible range were presented in

isolation.

Syllables were used in a variety of formal therapeutic activities, as well as informal settings at home. Combining individual vowels and consonants learned in isolation resulted in perception of a limited number of words. At this point, Wedenberg advocated part time use of hearing aid. Later, training progressed to short sentences formed by words already recognized by the child acoustically. Here speech reading could be

utilized by the child to supplement the information derived through the auditory channel. Wedenberg's method, then was directed toward development of auditory, speech

61 and language skills in children with either a congenital or prelingual hearing loss of severe to profound

proportions. In these respect it was similar to other auditory training methods proposed by Goldstein(1939), Whietehurst (1966), Watson (1961) and others. However his emphasis on management of the deaf child made Wedenberg's rehabilitative methods unique. Until World War II, the primary focus of auditory training was its use with severely / profoundly deaf children in effort to facilitate speech and language acquisition and increase their educational potential. Carhart Auditory Training Programme Raymond Carhart (1960) was among the earlier audiologist to develop auditory training for both children and adults and continued to expand auditory training after world war II. Carhart made one of the first extensive attempts to describe the role of auditory training in audiologic rehabilitation. His auditory training program is based on the belief that in case of pre-or perilingually hearing impaired children, since listening skills are normally learned in early life, the child may not move through the normal developmental steps important in acquiring these skills. In case of adults, when a hearing loss occurs, the auditory skills may become impaired even though they were intact prior to onset of hearing.

CHILDHOOD PROCEDURE: Carhart viewed auditory training for children as an aid in: - Developing a command of language. - Instructing the child to speak. - Encouraging better adjustment to the hearing world. Carhart auditory training outline for children consisted of four major stages of development. Stage 1. Development of Awareness of sound. Stage 2. Development of Gross sound discrimination Stage 3. Development of broad discrimination among simple speech patterns. Stage 4. Development of finer discrimination for speech. Stage 1. Awareness of Sound: The major goal of this stage is to recognize the presence of sound and attending to it with its importance in the child's world. The

62 child's attention is focused on loud sounds which he is likely to encounter in everyday situations. Stage 2. Gross sound Discrimination: This stage involves demonstrating with various noise makers that sounds differ. The main aim is to differentiate auditory signals that grossly differ produced by noise makers like bells, drum, tumbler, cymbals, horns, whistles etc. Special attention is given to developing the child's ability to perceive finer types of discrimination task that include variation infrequency, intensity, duration and sound composition of stimuli used. Stage 3. Broad Discrimination among simple speech pattern: The child moves to this stage only when he has demonstrated skill in recognizing the presence of sound and perceiving gross differences between environmental signals (non verbal stimuli). Here the activities are directed towards learning gross discrimination from speech signals. The child is trained to distinguish differences between vowel sounds with grossly dissimilar phonetic elements (i.e. /u/ vs /i/) and between short phrases which are closely related to everyday experiences such as "wave bye- bye" and "where's mommy?" Stage 4. Fine discrimination of Speech: This is the final stage which focuses on repeated drills which train the child to recognize subtle differences between similar vowels and consonant sounds as well as integrating his expanding vocabulary to permit quick and accurate understanding of speech.

ADULT PROCEDURES: As the adult person with hearing loss retains a portion of their original auditory skills, Carhart recommended that auditory training with adult focus on re-educating a skill diminished as a consequence of the hearing impairment.

Initially, Carhart felt that it was important to establish "an attitude of critical listening" in the individual. This involves being attentive to the subtle differences among sounds and can involve a considerable amount of

drill work on the perception of phonemes that are difficult for the adult with hearing impairment to perceive. List

of matched syllables or words which contain the troublesome phonemes, such as 'she'- 'fee', 'so'- 'tho', 'met' - 'let' or 'mash' - 'math' are read to the individual, who repeats them back.

Such training should also include phrases and sentences with the goal of developing as rapid and precise a recognition of the phonetic elements as is possible within the limitations imposed by the person's hearing loss. Speech reading combined with a person's hearing was also encouraged by Carhart during a portion of the auditory training sessions.

63 Carhart recommended auditory training sessions for adult should be conducted in three situations as follows: i) Relatively intense background noise. ii) The presence of a competing speech signal iii) Listening on telephone. According to Carhart the use of hearing aids is vital in auditory training and he recommended that they be utilized as early as possible in the

auditory training programme. ERBER (1982) APPROACH: A flexible and widely used approach to auditory training was designed and described by Erber primarily for use with children. This adaptive method is based on a careful analysis of

a child's auditory perceptual abilities which takes into account two major factors: 1. The complexity of the speech stimuli to be perceived (ranging from individual speech elements to connected discourse) and 2. The form of response required from the child i.e. i) Detection of sound, ii) Discrimination of sound, iii) Identification of sound and iv) Comprehension of sound.

Once the child's auditory capabilities are determined, an auditory training program is outlined by establishing goals and beginning points for therapy.

Erber also described three general styles which the clinician may use during auditory training, depending on the communication setting. 1.

Natural conversational Approach: This approach describes as I.

The teacher eliminates visible cues and speaks to the child in as natural a way as possible, while considering the general situational context and ongoing classroom activity. II. The auditory speech perception task may be chosen from any cell in the stimulus response matrix, for example sentence comprehension.

64 III. The teacher adapts to the child's responses by presenting remedial auditory task in a systematic manner derived from any cell in the matrix. 2. Moderately structured Approach: I. The teacher applies a closed set auditory identification tasks, but follows this activity with some basic speech development procedures and a related comprehension task. Thus the method retains a degree of flexibility. II. The teacher selects the nature and content of words and sentences on the basis of recent class activities. IV. A few neighboring cells in the stimulus response matrix are involved (for example, word and sentence identification and sentence comprehension) 3. Practice on specific tasks: I. The teacher selects the set of acoustic speech stimuli and also the child's range of responses, prepares relevant materials, and plans the development of the task- all according to the child's specific needs for auditory practice. II. Attention is directed to a particular listening skill, usually represented by a single cell in the stimulus response matrix (for example phrase discrimination).

Recent Approaches to Auditory Training The basic intent of auditory training is to maximize the communication potential by developing to it's fullest the auditory channel of the person with hearing impairment.

The current approaches to auditory training vary considerably. According to Blamey and Alcantara (1994) it is possible to categorize them into four general categories, based on the fundamental strategy stressed in therapy. ANALYTIC

APPROACH: This approach attempts to break speech into smaller components like phoneme, syllable and word and incorporates these separately into auditory training exercises. 1. SYNTHETIC APPROACH: It emphasizes a more global approach to speech perception, stressing the use of clues derived from the syntax and context of a spoken message to derive understanding. Training synthetically involves the use of meaningful stimuli (words, phrases and sentences). 2.

PRAGMATIC APPROACH: It involves training the listeners to control communication variables such as the level of speech, the signal to noise ratio and the context or complexity of the message in order to obtain the necessary information via audition for understanding to occur.

65 3. ECLECTIC APPROACH: It includes

training that combines most or all of the strategies previously described. Any auditory training programme must have analytic, Synthetic or pragmatic

tendency which can be learnt

described as eclectic since more than one general strategy for the training of the hearing channel

typically is used with a given child or adult. Individual

and Group Auditory Training Auditory training conducted with a single person with hearing impairment is called as Individual auditory training and the training session conducted with more than one person or in a group with common problems is termed as Group Auditory training. There is some advantages and disadvantages of both individual and group auditory training. Oyer (1966) has cited many advantages and disadvantages of individual therapy Advantages of Individual Auditory Training : 1. Audiologists have more time with the client for repeated trials. 2. They have better situations in which to discuss adjustment problems. 3. Here a close personal contact between the hearing therapist and the hearing impaired child exist. 4. The therapist can give the child personal attention for long period of time. 5. It is easier to plan auditory training session's materials and activities. 6. Surrounding environment will be quiet and relatively free of distractions. 7. Easy to attract and maintain one child's attention as he is within arm's length. 8. Signal to noise ratio is improved. 9. It allows the teacher to maintain objects. 10. It may possible to solve perplexing auditory problems that otherwise might take weeks to diagnose and or resolve. Disadvantages of Individual Auditory Training: as Oyer cited as: 1. Lack of peer evaluation. 2. No psychological support from peers. 3. No opportunities to compare and contrast individual efforts with others.

66 4. No opportunity to perform socially in a practice environment. 5. Expensive way to teach for long periods of time to an individual. 6. It is exhaustive for both teacher and the child. 7. In this set up fearful children have problems. Advantages of Group Training; 1. In a Group Auditory training sessions child with hearing impairment learns- i) Sense of cooperation. ii) The importance of keeping quiet while someone else is listening, iii) How to behave socially during an interactive group conversation. 2. Here children with impairment can help one another, by offering suggestions, prompts, strategies or encouragement that might not be as motivating if providing by the teacher also. 3. It can simply an interactive teaching in some situations, during a breakdown in communication, the teacher may have more options, such as requesting a responsive from another child if persistent difficulty occurs. 4. Shy persons improve their personality in this system. Disadvantages of Group Auditory Training: i) In a group auditory training the homogeneity of the group is questionable. The children with hearing impairment differ in their degree of impairment, type of hearing loss, Age of onset, presence of other disorders , parental cooperation etc. Therefore, if a group is not homogeneous, a child's performance can be influenced by another child's activity. ii) Individual attention cannot be given in this type of training session. 2.4.3 Stages of Auditory Training Hirsch (1966), Ling (1976) and Erber (1982) promoted step by step Traditional approach. The stages of the auditory training is described below 1.

Awareness or Detection of Sound : It is the basic process of determining whether the sound is present or absent.

Child can be taught to associate the sound and its source. It helps to remain in contact with the surrounding acoustic world.

67

Administration Procedure: The child should be

instructed to raise the hand when a sound is heard or keep a peg on the ear and put it in a box. The child can be given practice for doing this with the teacher sitting in front of the child

at a distance of 3feet. Each sound should be given at conversational level and with mouth covering position. Visual clue may be provided. If the child is unable to hear the sound from 3 feet distance, present the sound from near the child's ear. If the child hears all the 6 sound from 3 feet go to a distance of 5feet and administrate the sound. Note the result of each case. 2. Discrimination of Sound: In the second stage of auditory training the children with hearing impairment have to perceive the difference between sounds in terms of acoustic qualities, intensities and duration. Administration

procedure: By presenting two or three sounds one after another and the child has to say whether they are 'same' or 'different'. Begin with the

sounds that are very different from each other and then go step by step to sounds which differ more finely from each other. 3.

Identification of Sound: This stage involves labeling or naming of what has been heard. Identifying a sound by pointing to the sound, pointing to a picture associated to the sound, pointing to a written word or sentence or repeating whatever is heard. Identification of speech stimuli is related to the child's developing awareness that objects have names and these names have acoustic representations.

Administration Procedure: Child has

to indicate which sound he/she heard. This could be done by getting the child to point out to the sound written on paper or by repeating it if

the child can say all sounds.

68 If the child has not yet learned to read, toys or pictures depicting the sounds can be used as: - A train sound for the sound / u/. - A baby doll crying for / a /. - A car for the sound / i /. - An aeroplane for / m /. - A snake for / s / sound. - A pressure cooker sound for / S / sound. 4.

Comprehension of Sound: It is the final stage of auditory training which involves understanding the 'meaning'. It depends on language skills. It implies that the child can acquire new information through hearing and can act appropriately on that basis.

This programme incorporates 'speech' as a stimulus. All the children may not reach the 'comprehension' level but the teacher should train their residual hearing allows. Administration procedure: Activities can be Picture description.

Following directions: use any activity where the child must follow instructions. E.g. Drawing two cows sitting under tree.

Conversation: Engage the child with conversation relevant to the topic. Story with comprehension questions: Tell the child a story and then ask questions about the story. 2.5 Auditory Verbal Therapy Auditory verbal therapy is the

application of techniques, strategies, conditions and procedures which help in the acquisition of spoken language through major focus on listening to the children with hearing impairment. It is a way of guiding parents to teach their children with hearing impairment to develop spoken language by stimulating their residual hearing. The Auditory verbal approach helps children with hearing impairment learn to listen. Their speech and language skills are allowed to develop in a natural way following normal developmental stages. "The goal of auditory-verbal practice is that children

69 who are deaf or hard of

hearing can grow up in regular learning and living environments

enabling them to become independent, participating, and contributing citizens in mainstream society." (

from Auditory Verbal International, Inc, 1987 : position statement) 2.5.1 Principles: The main principles of the Auditory verbal therapy is

as follows Use of one sensory channel i.e. Auditory ONLY (No lip reading). Detection of hearing impairment as early as possible. To ensure that medical and audiological management is thoroughly completed, including selection, modification and use and maintenance of appropriate hearing aid / Cochlear implant. To support children's auditory verbal development through One to One therapy. Family involvement must be present as they are the primary models for spoken language. To wear the aid ALL DAY EVERY DAY. Using natural sequential patterns of listening, speaking, spoken language and cognition to stimulate natural communication.

To help children integrate listening into their development of communication and social skills.

The ultimate goal is a well adjusted person who uses listening and speaking to successfully interact with other at home and school in the community and in the world. Ongoing evaluation of progress to ensure that the Auditory Verbal Approach is appropriate

and through diagnostic intervention, modify the programme when needed.

To

help those children monitor their own voices and the voices of others in order to enhance the intelligibility of their spoken language. To provide support services to facilitate the children's Inclusion or integration into regular education classes. 2.5.2 Importance of Auditory Verbal Therapy Auditory Verbal Therapy encourages the maximum use of hearing in

order to learn language and stresses listening rather than matching. Young children with hearing

70 impairment even with minimal amounts of amplified residual hearing can be taught to use. In this kind of therapy, children with hearing impairment can grow up in regular and learning environment. Stages of Auditory development : - Sound Awareness Association of Meaning to Sound Imitation and Expansion. Comprehension: Effective Responses to Language.

2.5.3 Role of a Teacher A teacher of a child with hearing impairment is also a team member of the intervention process with Auditory verbal therapy method. Next to the parents a child with hearing impairment spends most of the time with his / her teacher. The special teacher may guide his/her student at the classroom, in their home or in different extracurricular activities. In Auditory Verbal therapy method the child has to listen with his amplification device and speak what he learns. Therefore, the teacher should follow the aural oral method of communication in the classroom and follows the principles of oralism during his / her class. In the beginning of the classes the teacher should check the individual or the group hearing aid or the implant as the aid functions properly for the child. If there is problem in the aid he/ she should immediately refer them to the audiologist. The teacher should follow the recommendation of the audiologist or Speech Language pathologist for communication i.e. the teacher's advice will be always verbal. Not a single nonverbal cue will be given to child for their understanding. As such they should also counsel the parents as to communicate with the child verbally only. The teacher also guides the student's friends and peer group to talk orally among themselves. The teacher may follow the following activities of the auditory verbal therapy in the classroom: - At first presentation of auditory stimulus. - Auditory attention: signal "listen" - Provide uncluttered listening space

71 - Acoustic highlighting - Use visual clarifiers - Speak slowly - Allow processing time Those children with hearing impairment follow the instruction of the teacher, they can learn verbal language and can include in the mainstream society.

2.6 Auditory Training and Auditory Verbal Therapy The basic principle of the Auditory Training and the Auditory Verbal therapy is same. As the child with hearing impairment must have to learn to listen auditorily and to speak orally only. In both training sessions the use of amplification devise is must.

2.6.1 Prerequisites For success in Auditory training and Auditory verbal therapy the child with hearing impairment must have the following prerequisites.

1. Early Identification: Early detection of hearing loss and early intervention of the disorder is must for Auditory training and auditory verbal therapy for the use of critical age period.
2. Proper Amplification Device: The child should use the proper hearing aid and or any other amplification device like cochlear Implant.
3. Adequate residual hearing: The child will learn to listen and speak through maximizing their residual hearing with amplification technology.
4. Parental cooperation: Parent participation is vital to the success of Auditory- Verbal Therapy for two reasons: parents are the natural teachers of their child's language and the parents are always with their child so can be constantly encouraging language development.
5. Proper Audiological management- There should be good coordination among professionals of the Rehabilitation team with skilful therapist and parents.
6. Child's Intelligence and learning style.
7. Listening to speak: The child learns to speak through listening to natural sounding speech. Correct spoken models of language are crucial to teaching the child to monitor his/her vocalizations. Visual cues are not encouraged.

72 8. Assessment: Monitoring and evaluating the development of listening skills as an integral part of the development process. 9. Integration result: Appropriate amplification and Auditory-Verbal Therapy enables children with a hearing loss to develop auditory receptive skills (understanding language) in the short term that will translate via medium outcomes, such as attending mainstream school, into greater social independence and quality of life. 10. Presence of other prerequisites of normal speech and language development like i) Neuromotor Maturation, ii) Sensory Perceptual ability, iii) Physical and Emotional development, iv) Cognitive development and v) Communicative environment. 2.6.2

Challenges It is a huge challenge for the Rehabilitation professionals to have success in auditory training and Auditory verbal Therapy for the children with hearing impairment. There are many factors or challenges which play role in its success. i. Aspects related to Early Identification and Intervention: Those children with hearing impairment identified and fitted with hearing aid before the age of 6th month perform better in auditory training and Auditory verbal therapeutic task than those who are intervened after their 6th month of age. If intervened early they can utilise almost full critical age period like normal hearing children and can achieve the normal speech and language if the other factors play positive role to them. ii. Factors related to Degree of hearing loss: The amount of residual hearing is a factor for achievement in auditory training and auditory verbal therapy. The more the hearing loss, the more the problem to have normal speech through auditory training and auditory verbal therapy. iii. Use of Amplification device: The better use of amplification device, the better will be the prognosis of verbal development of the children with hearing impairment. Using binaural digitally programmable hearing aid is a better option than the analog hearing aid. Hearing impaired child with cochlear implant also has better performance than the children fitted with hearing aid. iv. Motivation: It includes motivation of teachers, parents and the child too. As without motivation the teacher could not be able to train the child with hearing impairment for auditory training and auditory verbal therapy. Teacher should motivate parents to play active part in the training process.

73 v. Cooperation between the teacher and the Parents or the caregiver: parents must follow the advice of the teacher for the training or therapy and practice the skill at home with the child. There should be a healthy cooperation between the child and the parent for positive development of speech and language. vi. Opportunity to practice and use learned skills: When a new skill is taught, it should be practiced before the skill can become generalised. In order to do this, the teacher and parents should create situations in which a newly learned skill can be practiced. Practice sessions should be distributed throughout the day so that the child does not get fatigued. vii. Establishment of Proper habit: The child must be taught to pay careful attention to sound. It is a great challenge for the audiologist to establish proper habit to attend to all sounds of the environment and act accordingly. viii. Methods used by the teacher: Approach of training and the therapy should be appropriate for the level and expectation of the child. Within therapy session use of games and activities may interest the child. ix. Health and emotional state of the child: Before fitting of the aid or cochlear implant the health and emotional state of the child should be checked and then the prosthesis can be fitted and auditory verbal therapy can begin. 2.6.3 Similarities

and Differences
Auditory training as a set of procedures aimed at helping the aurally handicapped become more proficient in attending to the sounds of speech, discriminating one from the another and effecting an increase in retention of sounds (Kelly 1953).

According to Alpiner 1978,
Auditory training consists of three facets: i) Discrimination of individual speech sounds ii) Hearing aid Orientation. iii) Improvement of tolerance levels.

Whereas

Auditory-verbal therapy is a method for teaching deaf children to listen and speak using their residual hearing in addition to the constant use of amplification devices such as hearing aids, FM devices, and cochlear implants. Auditory-verbal therapy emphasizes speech and listening.

Auditory verbal therapy enables deaf and hard of hearing children to participate fully in mainstream school and hearing society.

74 It is apparent that there are no differences between Auditory Verbal Therapy and Auditory training, however if we really understand the principles of both training there is a considerable differences between the two. Similarities Both of these approaches have the following factors in common: i) They aim to assist the hearing impaired child to communicate with their peers using spoken language. ii) For either of these approaches to be successful, early identification of the hearing problem is essential. iii) Once the problem is identified, therapy should begin as soon as possible. iv) Hearing aids or cochlear implants are used to enhance residual hearing ability. v) Both aim to develop spoken language as the most desirable means of living and learning in society at large. vi) Both of the approaches exclude sign language. vii)

Both employ current technology and follow a number of similar clinical and educational

programme. Differences There are, however significant differences in those approaches. i) In the auditory-verbal approach, much of

the focus is on speaking and sound production. The teacher uses different types of 'modeling' to show the child how to speak correctly.

For example, a teacher may use the highlighting model to correct partially incorrect words or an Expansion model that fits in the gaps when a child skips a word or phrase.. But in the auditory-Training programme, the focus on listening is much more important. ii) In the auditory verbal therapy, the family is intimately involved in the learning process, and at least one parent must attend therapy sessions so that they can learn how to continue the learning process at home. In this approach, the parent becomes the teacher. In the auditory training programme Audiologist guide the child and the parent how to listen, discriminate, identified and comprehend all the sounds of the environment.

75 iii) Acoustic conditions of the home are very favorable to Auditory verbal therapy. In auditory training ambient noise level should be less than speech signals because ambient noise degrades speech signal. .

A clear speech is essential to learning. iv) Auditory verbal therapy involves children in abundant intervention with normal hearing peers,

but in auditory training it is not essentials. v)

Auditory verbal practice is to seek admission to regular school from the earliest possible stage.

In auditory training child is trained to comprehend speech and other signals from the environment not only for trying to include or integrate in normal school but also to receive the alarming noise from the environment. 2.7 Speech Reading

2.7.1 Concept Jacob's (1982) defines Speech Reading as 'a visual oral-language communication skills that enables a person to obtain linguistic information by watching the sequential, articulatory movements of a speaker's lips, jaws, adjacent facial musculature and facial expressions. According to Nitchie Speech reading is the act of understanding a speaker's thought by watching the movements of his mouth. There is a difference of speech reading from lip reading. Lip reading refers to the more analytical visual distinctive feature recognition process i.e. perception of visemes. While speech reading encompasses all of the other processes necessary to comprehend the spoken language. 2.7.2

Importance Speech reading or Lip reading can be called as a silent mode of verbal communication. The purpose of Lip reading is to provide visual cues to aid in the perception of speech. Not only have the deaf persons, person with normal hearing also communicated with lip reading. Sometimes we try to take some verbal information from a distant person through speech reading and sometimes we hide the oral movements of speech for not to give secrete information to unwanted persons. For the persons with hearing impairment Speech reading can be included in their total communication approach. As the deaf person get some verbal information through speech and some through speech reading. The degree to which persons with hearing impairment depend on vision for information is related to the extent of their hearing loss. According to Ross (1982), there is a world of difference between the persons who are deaf, who

76 must communicate through visual mode i.e. speech reading and persons who are hard of hearing, who communicate 'primarily' through an auditory mode. There is some evidence to suggest the visual recognition of consonants can be improved with a concentrated programme of lip reading instruction (Walden, Prosek, Montgomery, Scherr, and Jones, 1977). The development of these skills, however, can often be discouraging for the hearing impaired adult. The expectations of a client are usually unrealistically high when they first attend aural rehabilitation sessions. Discovering that the majority of English sounds are not visible is often enough to discourage or dishearten even the most enthusiastic client. This emphasizes the need for educating individuals regarding the limitations of using lip reading as a substitute for auditory information from the onset of the rehabilitative sessions. Even though persons with cochlear implant recognize some speech auditorily, the cochlear implant's most important role remains that of speech reading enhancement. Most cochlear implant persons recognize significantly more speech in a vision plus audition condition than an audition only condition. Speech reading training helps the patient relate the electrical signal to the corresponding visible articulatory behaviour.

2.7.3 Prerequisites

The Prerequisites that affect Speech reading process usually fall into five general areas as related to the Speaker, Speech reader, Environment, the Signal or Code, and other factors.

- a. **SPEAKER**
 1. **Familiarity of the Speaker:** A positive correlation was shown to exist between speaker - listener familiarity over 80 years ago (Day et al. 1928). Speech reading performance will be good when the speaker is familiar to the speech reader.
 2. **Facial expression, Gestures and Physical position:** Facial expression gives the cues about the context and situations. Speakers who used appropriate facial expression, common gesture and who positioned themselves face to face or within a 45 degree angle of the listener facilitated communication for speech reading (Stone, Berger 1972, 1957).
 3. **Articulation or Lip movement:** Speakers who were precise and not exaggerated articulation are the easiest for the speech reader to understand the message (Davis et al. 1972).

4. **Rate of Speech:** If the speaker's normal speaking rate exceed or reduced, the listener's visual reception capabilities or exaggerate speech production then it hampers comprehension.
5. **Distraction:** The speaker should avoid simultaneous oral activities such as chewing, smiling, yawning, sneezing etc. while convening with a hearing impaired person. The 'making effect' of these coincidental activities may complicate the speech reading task.
6. **Gender:** Berger (1977) suggested that male speech readers sometimes find difficulty with female speaker and vice versa. Gender related variables such as moustaches or the use of lipstick may influence speech reading process.
7. **Extent of Image:** Impression or the image of the speaker on the speech reader also plays an important role in speech reading.
8. **Associated Body movements:** Nitchie (1972) suggested that speech reading will be more productive where the speech reader can observe appropriate nonverbal communication modes like head and body movements of the speaker.
9. **Language spoken:** Familiarity of language is an independent variable that influences the interpretation of visual cues. Language spoken by the speaker should be common or familiar to the speech reader.
10. **Others like suprasegmental aspects of speech, speakers presentation and style etc. may influence speech reading.**

B. SPEECH READER

1. **Hearing capacity:** Persons with significant amount of residual hearing have the potential to speech more successfully than those with very limited hearing due to availability of auditory cues contained in speech. Other factors like auditory perception abilities, age of onset of hearing loss, progressively, site of lesion etc. may influence speech reading.
2. **Age and Language skills:** Speech reading proficiency tends to develop and improve throughout childhood and early adulthood and appears to be closely associated with the emergence of language skills (Berger et al. 1978). Even though the speech reading abilities are not fully developed in younger children, they may use speech reading to some extent even infants also. Other individuals do less speech reading than their counterparts who are between the age ranges of 21 to 30, may be due to decreased visual acuity with aging.

78 3. Intelligence: Much reduced intelligence level may result in poor speech reading performance (Smith et. al.1964) 4. Personality traits: Highly motivated clients tend to speech read more effectively than to unmotivated clients. 5. Visual performance proficiency: a) Visual acuity: Even slight visual acuity problem had an appreciable negative effect on speech reading scores. Visual acuity must be at least 20 / 30 to enable the speech reader to see the five sequential articulatory movements of speech. b) Visual problem: Like color blindness may affect speech reading through "Eye glass speech reading aid". c) Visual Memory: The speech reader must follow the following sequential pattern for visual memory. i) Perception of the articulatory patterns from the speaker's mouth and jaw movements, ii) Retention of the patterns sequentially in short term memory. iii) Coding into linguistic units by using inner language coding system. iv) Synthesize the information in permanent memory for final message identification. v) Match with information in permanent memory for final message identification. d. Visual perception of consonant and vowels: The visual perception of place of articulation of consonants, vowels and diphthongs is very important to speech reading. 6. Synthetic ability of the Speech Reader: Perceptual closure i.e the ability to identifying the patterns of speech and the conceptual closure i.e the ability to identify the message are the two synthetic abilities which requires speech reading. 7. Flexibility and Emotional attitude: It includes cooperation of parents, educational and therapeutic management etc. 8. Type of Intervention: Speech reading performance improves with cochlear implant / tactile devices as compared to conventional hearing aid or without hearing aid. 9. Motivation: Better speech reading skill was found among children who reported a positive attitude towards speech and speech reading by their parents and deaf peers. Interest and motivation should strengthen speech reading and overall communication skills.

79 C. ENVIRONMENT: 1. Distance and viewing angle: Speech reading ability is optimal when the speaker is about 5 feet distance from the speech reader with face to face conversational situation. For most speech readers, watching the speaker at horizontal viewing angle of 0-45 degree is preferable. 2. Competition: simultaneous auditory and visual competition can have an adverse effect on speech reading under certain condition. 3. Light and Illumination: For most optimal speech reading, light and illumination should provide a contrast between the background and the speaker's face. 4. Cues: Speech reading ability increases when the speech is accompanied by pictorial, auditory, contextual, situational and environmental clues. 5. Coping up with the situation: The speech reader's ability to visually scan and cope up the situation and understand the speaker's role will provide an attention which is set for social or formal communication. 6. Auditory distractions: The effect of noise on speech perception by the hearing and hearing impaired participants and the person with hearing impairment ability to monitor his or her vocal modules in noise are also factors to be considered. 7. Visual Distraction: It also affects speech reading by drawing the speech reader's attention away from the force especially if the distraction is more interesting than the speaker. 2.7.4 Challenges There are many variables which may influence or challenge the Speech reading. These are: 1. Amount of Self teaching: speech reading does not always have to be taught, though the individual's skill can be improved through instructions. Numerous hearing impaired individuals have developed a fair degree of proficiency without formal instructions. 2. The adequacy of the hearing aid or aids: Hard of hearing adult need to speech reading because all hearing aids have certain physical limitations, by this he will not perceive accurately all of the consonant sounds.

80 3. Extent of Hearing loss: Severe sensorineural hearing impairment (70 dB or more) patient will confuse many speech sounds or miss them altogether even with hearing aid. He must look as well as listen. 4. Pattern of Loss: The high frequency loss cases (sharp fall off at or beyond 1 KHz) need to combine speech reading with hearing in order to understand voiceless consonants. 5. Nature of Loss: In retro cochlear hearing loss cases the confusion of perceiving speech can only be straightened out through speech reading. 6. Individual differences in ability in mastering skills: Those people are not eye minded or will not automatically look as well as listen, they have not acquired any degree of speech reading skills though sufficient training are provided to them. 7. Knowledge of Language: To develop speech reading, he must have mastered the verb-tense system and syntax of his language which are redundant, patterned and rhythmical. 8. Nature of instruction: The teacher has to ascertain the child's true needs to teach the beginning skills of recognizing visible sound movements and known vocabulary and ideas to children. Beside there are some limitations of Speech Reading such as Low visibility of speech sounds, Homophonous sounds, Rapidity of normal speech, Transition effect, inter subject variability with sound formation and environmental limitation Therefore, it is apparent that numerous factors have an impact on speech reading success. The clinician should be familiar with these and take each into account when planning auditory training with respect to speech reading. However few factors are yet to be understood with its impact which requires further research development. 2.7.5 Role of Teacher As the 'Speech Reading' is an inherent linguistic activity (Boothroyd, 1988), the deaf students must learn the rules of language by which they are exposed to speech reading. Therefore it is the duty of the teacher of the deaf to develop language in deaf students. Without this he / she is unable to fill in the gaps providing information not obtained through speech reading or hearing (Bevan, 1988). Teacher should speak clearly with normal prosodical features as such most of the speech parameter can be intelligible to the students. As speech reading skills is a visual

81 communication process, the classroom of the deaf student should be properly illuminated so that the speaker's face can be properly visible during communication. A student with hearing impairment depends on his / her teacher for learning Speech Reading. Originally there were four methods of teaching speech reading in United States (O'Neill & Oyer, 1981). These are Bruhn Method (1929), Kinzie method (1931), Nitchie Method (1912) and Jena Method (Bunger 1944). First three methods were nurtured by normal persons and later these were used for persons hearing impairment. These original methods are now seldom used. Currently two general approaches of speech Reading is instructed by the teacher, i.e i) Analytic Approach : Where each of the basic parts of speech be perceived before an entire words, sentence or phrase (the whole) can be identified

or ii) Synthetic approach: It emphasizes that the perception of the whole is paramount regardless of which of its parts is perceived visually. Here the sentence / phrase to be the basic unit and these are the backbone of visual speech perception. Recent trends in teaching speech Reading: Recently apart from Acoupedic approach which emphasizes auditory channel only, speech reading appears to develop synergistically with the acquisition of auditory and Language skills (Pollack, 1964). Teacher may use holistic approach (Yoshinaga - Itano, 1988) to teach children with hard of hearing to Speech read. It focuses on each individual child's motivation, tolerance and sense of responsibilities for communication. Alpiner and Mccarthy (1993) and Rodel (1981) recently introduces Bisensory stimulation where both auditory and visual input are favoured. Therefore, teachers mainly allow speech reading to develop naturally in conjunction with the acquisition of auditory, speech and linguistic skills. 2.8 Let's Sum Up The major goal of aural rehabilitation is the improvement of communicative abilities of the persons with hearing impairment. Early identification, proper audiologic evaluation and good medical care are essential to the remediation of hearing impairment. Generally sensorineural hearing losses are primarily aided through audiologic rehabilitation only where auditory speech recognition or hearing clarity is usually affected. The structure of language is unique to the human beings only.

We have developed the auditory system and vocal mechanism through which language is customarily learned and communicated.

Oral communication involves a number of key components that originate with a source or speaker who has both a purpose for communication and the ability to properly encode and articulate the thought to be conveyed.

82 The human baby appears to be born with "preexistent knowledge" of language - specialized neural structures in the brain that await auditory experience with language to trigger them into functioning. If a child is deprived of language stimulation in his critical age period they will never attain his or her best potential language function due to hearing impairment or lack of language experience. Auditory perception of speech and non speech signal involves only one sensory system i.e. hearing or auditory system. Therefore, it is called as unisensory approach of auditory perception. Speech perception implies understanding and comprehension and the reception of speech signals by the auditory mechanism is only the first step in its perception. Perception or comprehension of speech may be thought of as involving a number of components. Among these are: DETECTION, DISCRIMINATION, IDENTIFICATION, ATTENTION, MEMORY, & CLOSURE. The persons with hearing impairment cannot perceive the speech signal as they are not able to receive and process the coded acoustical information of the speech signal like the person with normal hearing. The speaker's mouth movements, facial expressions and hand gestures as well as various aspects of the physical environment in which the communication takes place, are potential sources of useful information for communication. The person with hearing impairment is much more dependent on these visual cues for communication than the person with normal hearing. The degree to which persons with hearing impairment need visual information when conversing is proportional to the amount of information that is lost due to hearing impairment. Visual information may be transmitted by means of a manual or an oral communication system. The approach which includes more than one sense organ for perception of speech is termed as Multisensory approach. For perception of speech children with hearing impairment depends on vision and tactual sense along with their residual hearing ability. Auditory training is a systematic training of the residual hearing for the improvement of auditory abilities. Primary goal of auditory training is usually to maximize receptive communication ability by using audition. When it is conducted with a single person with hearing impairment it is called as Individual auditory training and the training session conducted with more than one person or in a group with common problems it is termed as Group Auditory training. The stages of the auditory training as per Traditional approach (Hirsch (1966), Ling (1976) and Erber (1982)) are: Awareness or Detection of Sound, Discrimination of Sound, Identification of Sound,

83 Comprehension of Sound. Auditory verbal therapy is the application of techniques, strategies, conditions and procedures which help in the acquisition of spoken language through major focus on listening. The goal of auditory-verbal practice is that children who are deaf or hard of

hearing can grow up in regular learning and living environments

enabling them to become independent, participating, and contributing citizens in mainstream society.

The primary stages of auditory

development are: Sound Awareness Association of Meaning to Sound Imitation and Expansion. Comprehension:

Effective Responses to Language. Sound Awareness Association of Meaning to Sound Imitation and Expansion.

Comprehension: Effective Responses to Language. A teacher of a child with hearing impairment is also a team member

of the intervention process with auditory verbal therapy method. The teacher may follow the auditory activities of the

auditory verbal therapy in the classroom with different acoustic and visual clues. The basic principle of the Auditory

Training and the Auditory Verbal therapy is same. As the child with hearing impairment must have to learn to listen

auditorily and to speak orally only. It is a huge challenge for the Rehabilitation professionals to have success in auditory

training and Auditory verbal Therapy for the children with hearing impairment. There are many factors which play role in

its success. As per Jacob(1982), Speech Reading is a visual oral-language communication skills that enables a person to

obtain linguistic information by watching the sequential, articulatory movements of a speaker's lips, jaws, adjacent facial

musculature and facial expressions. Lip reading refers to the more analytical visual distinctive feature recognition process

i.e. perception of visemes. While speech reading encompasses all of the other processes necessary to comprehend the

spoken language. The purpose of Lip reading is to provide visual cues to aid in the perception of speech. Not only have

the deaf persons, person with normal hearing also communicated with lip reading. The Prerequisites that

84 affect Speech reading process usually fall into five general areas as related to the Speaker, Speech reader, Environment, the Signal or Code, and other factors. It is the duty of the teacher of the deaf to develop language in deaf students. Without this he / she is unable to fill in the gaps providing information not obtained through speech reading or hearing (Bevan, 1988).Teacher should speak clearly with normal prosodical features as such most of the speech parameter can be intelligible to the students. 2.9 Check Your Progress A. Answer the following questions. 1. What do you know about Audiologic rehabilitation? 2. Describe human communication model. 3. What are different approaches of auditory perception? Discuss any one. 4. Describe the process of perception of speech stimulus. 5. What are the different approaches of auditory training? Describe Carhart Auditory training approach. 6. Define Auditory training. Mention importance of auditory training. 7. Differentiate between Individual and group auditory training. 8. Describe the stages of Traditional auditory Training approach. 9. Mention the factors affecting Auditory training. 10. What do you mean by Auditory Verbal Therapy? Describe the principles and importance of Auditory verbal therapy. 11. Discuss the role of a teacher in Auditory verbal therapy. 12. Mention the similarities and differences between auditory training and auditory verbal therapy. 13. Define Speech Reading. Mention importance and prerequisites of speech reading. 14. How does a teacher of children with hearing impairment teach speech reading to his student? 15. Describe the factors affecting teaching speech reading skills. B. Write short notes on the followings: 1. Classification of hearing impairment.

85 2. Auditory Listening. 3. Adult auditory training. 4. Group auditory training. 5. Prerequisites of auditory training and auditory verbal therapy. 6. Factors influencing auditory training and auditory verbal therapy. 2.10 References 1. Jerome G. Alpiner, Patricia A. 87 3.1 Introduction All hearing impaired children experience speech and language problems owing to their reduced hearing capacity. The speech and language problems may range from no speech and language at all to some deficits in speech production and language ability of the child. As we have already learnt speech is oral medium of expressing language. Speech problems may include incorrect production of speech sounds, inappropriate voice quality and resonance. These problems arise due to inappropriate auditory feedback. All these problems can be remediated with early assessment and intervention. The child needs to undergo a detailed hearing, speech and language evaluation followed by fitting of an appropriate amplification device. This is again followed by a well-planned speech and language therapy. The mechanism of speech production is a very intricate process involving the vocal tract and respiratory system. To understand the mechanism of speech production mechanism appropriately, the basic characteristics of speech sounds have to be first understood. The acoustics of speech involve characteristics like frequency, intensity, duration and resonance. Various speech intervention strategies are described in the literature. These can be carried out in various settings such as therapy center, school and also at home. Many strategies are designed for individual child, depending on specific needs of the child. Also there are strategies which can be carried out in group settings. Each strategy have its own advantages and disadvantages. Speech training can be imparted by a single trainer/specialist or a group of trainers can be involved. The group can either consist professionals from same specialty or can be from varied specialties such as speech therapist, special educator, psychologist etc. The team teaching concept needs well skilled professionals and a very good planning. Moreover it yields a very satisfactory outcome. 3.2 Objectives At the end of this unit, students will learn about: 1) Various speech intervention strategies. 2) Formulation of lesson plan.

88 3) Acoustics of speech - basic characteristics involved in the mechanism of speech production 4) Techniques to elicit production of vowels and other speech sounds 5) Importance of individual training and group training 6) Group teaching. 3.3 Approaches to Teaching Speech Literature has description of many speech teaching approaches and activities. Before understanding each approach we should remember that speech therapy can be made successful when: 1) Done at an early age(starting within 3 years). 2) Done after complete assessment of speech problems and identification of child's current level. 3) Done after fitting of appropriate amplification device. 4) Done within a stimulating environment. 5) Done following a constructive lesson plan wherein targets are set and achieved. 6) Done with appropriate child specific selection of stimulus, reinforcers and speech therapy tools. All the approaches are based on certain principles. Few are listed below briefly: 1) Speech learning is developmental and follows a sequence even in hearing impaired children. Certain sounds develop first and certain come later, e.g. children are able to say /b/ much before saying /t/ or /r/. 2) Speech is a learned behaviour which needs to be taught. 3) Better residual hearing gives best results. 4) Speech therapy sessions should be repetitive and fun filled for the child. Let us learn the approaches now: Hearing Impairment causes delay in acquisition of speech and language. The degree of hearing loss, age of child, onset of hearing loss have effect on the speech and language skills of the child. By large almost all children with hearing impairment need some amount of speech therapy. The early it is started more successful results are obtained.

89 3.3.1

Auditory global approach For correct acquisition and production of speech the child must have an intact auditory channel. The child listens to adult speech, internalizes them and then starts producing them. The journey from starting to produce a speech sound to fully master its production needs lot of self- corrections by the child him/herself. He/she hears to adult speech, imitates and learn from it as a model then produces it correctly by self- corrections (with the help of auditory feedback). However the child also uses other cues such as visual, kinesthetic along with auditory cues for speech acquisition. In case of children with hearing impairment mainly the auditory channel is used, along with the other sensory channels. The selection of modality depends on the child's hearing level after amplification. For example in case of minimum benefit from amplification device, the visual, and tactile modes are largely used to supplement the minimum residual hearing. The term "auditory global" was given by Calvert and Silverman (1975). It mainly stresses the use of auditory method with minimum or no use of visual and tactile cues. The authors also emphasised early and continuous use of amplification device, comprehensive intervention at school as well as home, natural methods to model and teach speech and use of connected speech.

3.3.2 Auditory-Oral Approach In this approach speech reading and contextual cues are used along with residual hearing for understanding speech. The child is taught to combine hearing cues (with amplification device) with speech reading (lip reading cues) and understanding the context in which the conversation is carries out. This is a very useful approach for children with restricted residual hearing. However this approach needs lot of practice by the child. Moreover in absence of contextual cues, understanding becomes difficult. It can be easily incorporated by teachers in classroom during teaching sessions. The teacher can model the child how to speak, utter certain sounds/words etc. When used with young children after early identification and intervention, they can be easily mainstreamed.

3.3.3 Aural-Oral Approach The focus is on speaking and sound production. The therapist uses different types of 'modelling' to show the child how to speak correctly.

90 The child's aural skills (auditory) are developed for attaining oral (verbal) skills. In

this approach the following is advocated and used by therapist/teacher: 1) Directly talking with the child 2) Use of simple speech 3) Use of facial expressions and body language 4) Repeat the key words 5) Speak things from the child's context

3.3.4 Auditory verbal approach It is a parent oriented approach, where the child's residual hearing is maximally used to understand speech of others and to learn to use spoken language for communication. In this approach the audition is taught in four classical levels: detection, discrimination and identification. VT is based on some fundamental principles like early detection, fitting of appropriate amplification device, regular assessment and therapeutic management, direct parent involvement, mainstreaming the child into regular educational system. With improved technology in amplification devices, it is very much possible to teach the child only through auditory channel.

3.3.5 Multi-sensory syllable unit approach As the name suggests the auditory channel is accompanied by other sensory channels. It is useful for children with limited residual hearing. Visual and tactile stimulation is used with auditory stimulation. Written forms /orthographic representation of sounds, words are used along with oral speech. Labelling is used for all the vocabulary in the child's environment.

3.3.6 Ling's approach Developed in 1976 by Ling. In this approach maximum use of residual hearing is advocated. In this approach the child is taught to understand speech of others as well as correct own speech production by using residual hearing. Two principals of Ling's approach are: 1: The hearing impaired child should be taught to develop speech in the same order as a normal hearing child will follow. 2) The speech organs move rapidly and precisely during speech production, which should be taught to hearing impaired children so that they can produce correct speech.

91 Speech is taught at phonetic and phonological level. e.g. In phonetic level - nonsense syllables, repeated syllables are used. Then

this skills learned

are adapted to the phonological level. Initially vowels are taught in isolation, then consonants are taught

in different contrasts of place and manner. 3.4 Formulation of Lesson Plan Lesson plan is a brief rehabilitation plan for the hearing impaired child with some short term goals and one long term goal. The lesson plan is a road map for the teacher and therapist which guides them to carry out the therapy. It also contains information regarding the procedure which will be used to attain the goals, activities under these procedures are to be planned beforehand. The formulation of lesson plan is kept as realistic as possible. Selection of goals depend on the child's current performance, age, associated disorders and parental support. 3.4.1 Short term goal- these are planned for short time period.e.g. 15 days /30 days.

Usually easy and small targets yield better motivation to both the therapist and the child. At a time 3-4 short term goals can be achieved. These are expected to be achieved in the predefined time period. Once achieved, the task complexity is increased. In case of failure, the step may be repeated with an altered procedure and tools. The STM should be measurable, clear, realistic and verifiable. 3.4.2 Long Term Goal- It is a target or goal which is a final destination or level at which we want the child to reach over a longer period of time .e.g. six months. So that he matches his peers as closely as possible and can be gradually mainstreamed. 3.4.3 Activities for teaching various vowels and consonants The teaching can generally be carried out using the following techniques: 1. Modelling the speech sound to the child. Initially only auditory mode can be used, if the child failed to do so, other modes can be introduced. e.g. for teaching the child to produce /i/, the sound can be shown in writing to the child and the therapist can keep on modelling its production, repetitively, till the child starts showing attempts to produce it. If the child has limited residual hearing that is has limited benefit from amplification device cues of visual and tactile cues can be introduced. The

92 therapist can show the production of the vowel to the child, can physically guide the child's articulators to help produce the sound. The child has to be reinforced upon correct production of the sound. The sound is first taught in isolation then in combination with other vowels, other aspects like long vs short vowel are introduced later. 2. Imitation- Imitation of the therapist's vowel/consonant production is encouraged. The child is asked to listen and produce the target sound. In case of limited residual hearing, use of visual/tactile cues along with auditory cues give opportunity for the child to imitate the sound. 3. Repetitive drills- CV combinations, CVC combinations are practiced through speech drills. The combination of CV is also altered to make all possible combinations of the target sound. /pa,pi,pu,po,pe/ and /pa,pa,pa,pa/. Though the sounds are meaningless, these ensure improvement in the precision of movements of articulators. 4. The teaching usually starts with vowels. Initially the child may be taught just to vocalise and extend it with all the vowels.e.g /aaaaaaaa//iiii...../ etc. The therapist should always encourage a good quality of voice which sounds natural and pleasing. It should be loud enough, not nasalised, and should be produced with adequate mouth opening. Simultaneously the therapist has to encourage the child to monitor his/her own voice through auditory feedback. 5. In case of consonants, the easily visible consonants, voiced consonants are selected first.e.g. /b/ has to be taught earlier than /g/ or /p/. However in some children, there can be some amount of speech already present, which can be utilised to expand his/her utterances. The therapist can refer to the normal developmental sequence of consonants, and select the consonants serially. E.g. the production of consonants like /s/,/ch/ and /t/ develop after 4 years of chronological age, the same will apply to hearing impaired children, it's pointless to teach a 2 years old to produce the sound /s/!! 6. Once the child has learnt to produce consonants in isolation, gradually these can be taught into higher units, bisyllabic words, words, phrases etc. E.G. Once the child has learnt to say /ta/, he/she can be taught to say /tata/ meaningfully. 7. For carrying out above activities tools like mirror, tongue depressors, hand gloves, candle, paper bits, and graphical representation of the letters on flash cards are extremely useful. The use of toys and other reinforcers make the activities fulfilled and interesting.

93 8. Parents and caregivers should be actively involved in the training activities and should be counselled to practice the learnt sounds at home. 9. It's helpful to set targets and expected responses to achieve success. E.g. If our target consonant is /t/,the child should be able to utter it 3 times out of 5 trials, which ensures us to take the child to the next level. 10. All the learned vowels and consonants should be retrained at a regular interval to achieve stabilisation. 3.5

Orientation to Acoustics of Speech 3.5.1 Nature of sound Sound is variations in air pressure detectable by the human ear. Pressure varies through time at a particular point, and over space at a particular time, as molecules of air collide (condensation) or move apart (rarefaction). Fig. 1: Representation of fluctuations in air pressure such as those caused by a vibrating tuning fork. Waves and energy movement, or variation at a particular point, can be plotted as a waveform on a graph, as in above figure Fig.1.The variation in pressure at a given point gives a sine wave for pure sounds involving simple harmonic motion (SHM).The amplitude (the amount of maximum displacement from zero) of the wave reflects the highest pressure involved, and therefore the acoustic energy. Relations between frequency (F), period (P), wavelength (w) and speed of sound (c):

94 $F = 1/P$ For example, a wave with a period of 1/100th of a second has a frequency of $F = 1/0.01 = 100$ Hz (Hertz = cycles per second) $w = c/F$ The standard speed of sound is 330 m/s. For example, a wave with a frequency of 100Hz has a wavelength of $330/100 = 3.3$ m Fig. 2. Representation of a sinusoidal Waveform There are various types of sound sources a. Tuning fork - periodic b. Vowel sounds - quasi-periodic. Fig. 3: c. Flow of water - continuous random noise d. Fricative - random within certain constraints. Fig. 4: e. Hammer hitting table - transient f. Stop consonant - transient + noise. Fig. 5: Resonators and Filters Natural frequencies and resonance - different objects more or less tuned to specific frequencies - can act as filters. Filters have centre frequency and bandwidth - the range of frequencies passed by filter not more than 3dB down on its maximum amplitude. The bandwidth of a filter may be relatively narrow or broad.

95 Source + Filter theory: Vowel Sounds The vocal tract acts as a complex variable filter. Into this is input a signal from the glottal source (for voiced sounds). Fig 6 shows a glottal source wave for a vowel, i.e. a complex wave with numerous harmonics which rapidly decrease in amplitude as frequency increases (12 dB/octave). (b) Vowel sounds seen as product of glottal source and variable filtering effect of supraglottal tract. So, the same vowels have the same gross spectral shape, irrespective of the fundamental frequency f_0 of the source. Fig. 6 filtered once ... filtered twice and filtered 3 times Fig. 8: Spectrum of a vowel sound shown as the product of the glottal source and the filtering effect of the supraglottal vocal tract. 3.5.2. Speech sounds

Speech sounds, just like any other sound, are rapid fluctuations in air pressure. Speech sounds are generated when air is made to move by the vocal organs, While speaking, acoustic energy is radiated from the vocal tract. This acoustic disturbance, consisting of pressure fluctuations, causes the listener's eardrum to move rapidly in and out - in when the pressure is positive, out when negative. Thus acoustic energy is transformed into mechanical energy at the eardrum, This mechanical energy, and the information it contains, go through several more transformations before arriving as patterns of neural energy at the listener's brain, The processing of the information in the listener's brain results in the percept of sound. Speech waves The speech wave

is distributed, at any given instant, as a sound pressure wave in the air around the speaker, and can be looked at as pressure varying as a function of distance from the speaker.

In speech acoustics, however, it is more common to

96 consider the air pressure in a speech wave as varying not as a function of distance but as a function of time. This is equivalent to saying that at such-and-such point in space, the air pressure varies in such-and-such way over time.

Frequency It can be seen that the magnified speech wave consists of rapid variations in air pressure as a function of time.

Variations represent positive increases in pressure relative to atmospheric pressure and also negative. The variations are periodic - they repeat and are obviously complex, in that the air pressure can be seen to be varying simultaneously at several different frequencies. These frequencies can be roughly estimated visually as follows. Fundamental frequency

The rate of repetition of the complex wave is called its fundamental frequency (abbreviated F_0 , which is pronounced "eff-oh" or "eff sub-zero") and this wave therefore has an F_0 of 154 Hz. Fundamental frequency is an extremely important measure in acoustic phonetics in general. From the point of view of speech production, the F_0 corresponds to the rate at which the vocal folds vibrate. From the point of view of speech perception, had been in the vicinity of the waveform, an eardrum would have been going in and out 154 times per second as a response to these pressure fluctuations. Fourier analysis

One way of looking at the speech wave is as complex fluctuations in air pressure as a function of time. Another is as a spectrum, which shows exactly what frequencies are present with what amplitudes. Fourier's theorem shows that any complex wave can be decomposed into, or represented as, a set of sine waves, also called sinusoids, each with its own frequency and amplitude. The spectrum

Harmonics and Spectra Complex waves can be mathematically analysed as being composed of different sine waves (Fourier analysis). Vibrating objects don't usually vibrate at a single frequency, they have harmonics. According to when each harmonic starts, the different elements of a complex wave can be in different phase relations. Any complex wave can be analysed into the periodic elements of different frequencies of which it is composed. Result: the spectrum of sound. For example, the following spectrum is of the waveform

97 produced at the glottis in a vowel. Note the series of peaks or harmonics, occurring at integer multiples of the fundamental frequency f_0 . (d) Non-periodic sounds are more adequately represented not by line spectra but by a continuous spectrum. Fig. 7: Continuous spectra of non-periodic sounds: left [s] (peak at c. 5920 Hz); right [ʔ] (peak at c. 2700 Hz). The acoustic theory of speech production 107Db 5500Hz

produced at the glottis in a vowel. Note the series of peaks or harmonics, occurring at integer multiples of the fundamental frequency f_0 . (d) Non-periodic sounds are more adequately represented not by line spectra but by a continuous spectrum. Fig. 7: Continuous spectra of non-periodic sounds: left [s] (peak at c. 5920 Hz); right [ʔ] (peak at c. 2700 Hz). The acoustic theory of speech production 107Db 5500Hz

98 The theory that explains the radiated acoustics in terms of the vocal mechanism that produces them is called the acoustic theory of speech production, or source-filter theory. It was developed by the Swedish speech scientist Gunnar Fant. The source-filter theory describes speech production as a two stage process involving the generation of a sound source, with its own spectral shape and spectral fine structure, which is then shaped or filtered by the resonant properties of the vocal tract. Most of the filtering of a source spectrum is carried out by that part of the vocal tract anterior to the sound source. In the case of a glottal source, the filter is the entire supra-glottal vocal tract. The vocal tract filter always includes some part of the oral cavity and can also, optionally, include the nasal cavity (depending upon whether the velum is open or closed).

3.6 Strategies for Production of Speech : Modeling & Shaping through Auditory, Visual and Tactile Modalities

STRATEGIES FOR ELICITING SOUNDS

Strategies may have auditory, visual, and tactile components. However, some strategies may be exclusive to one modality. For example, manipulation is primarily a tactile strategy with a possible visual component. Phonemes should be taught first through audition. When discussing auditory strategies, it is important to discuss the four levels of auditory skills: detection, discrimination, identification, and comprehension. Detection is simply determining whether sound is present or absent. Through detection tasks, we can check whether hearing aids are working and set appropriately, alert students to the listening task, and determine which sounds are audible to the child. The response may be yes/no or a conditioned response (such as dropping a block in a bucket). The second level of auditory skill, discrimination, is determining the similarity or difference between speech sounds. Instructors often use this level as remediation or a check when the student makes an identification error. It is important to realize that some different discrimination tasks are difficult or impossible for children who are unable to categorize or make generalizations. The third level of auditory skill, identification, means providing a name or a label for what the student has heard. The student may respond by repeating the word, writing the word or sentence, or pointing to the stimulus being presented.

99 The highest level of the auditory skill hierarchy is comprehension. Comprehension tasks require that the student understand the meaning of auditory messages. It also requires the student to acquire new information through hearing, and then react appropriately. Unlike an identification task, the student must not only label the stimulus, but also must demonstrate understanding with a response that differs in content from the stimulus but is closely associated in some way (Eerber 1982). After using auditory strategies, visual strategies should be considered before moving to tactile strategies. Because the strategy employed is dependent upon the student's abilities, diagnostic results should be reviewed carefully. This will allow you to move quickly to strategies that will provide the student with success. Many times, strategies are used simultaneously. The most widely used strategy is that of imitation or demonstration. Imitation requires the student to repeat a target sound after one or more examples have been provided. Imitation is easily and naturally combined with other strategies when evoking sounds. For example, a sound may be presented without allowing the student to see your face. The student is required to produce the sound after one or two presentations. If the student is unsuccessful, the phoneme may be presented again, this time allowing the student to see your face. If this strategy is unsuccessful, imitation through tactile stimulation may be the next modality attempted. The tactile modality is usually the last teaching strategy used. Students can feel the tongue position for most vowels by placing a finger on the instructor's tongue, then placing a finger of the other hand on their own tongue. Another widely used strategy is moving from a known sound or "U set" to an unknown. This is accomplished through use of context, sound approximation, and analogy. Use of context means that facilitating contexts may be used as a beginning point for a lesson or in combination with other techniques to develop intelligibility. For example, if a student can produce /J/ in a few contexts (such as /Ju/ and /Ja/) but cannot imitate it in other contexts (/Jil/ or /Ju/), the instructor should indicate the words where the sound is correctly produced, then provide practice on the available facilitating contexts. Teaching through sound approximation is another technique of progressing from a known sound to an unknown sound. In this method, the instructor uses a phoneme the student can correctly produce as a point of departure for teaching the target sound. For example, say the target sound is /f/ and the student can produce /si/. Have the student gradually move the tongue back until /f/ is produced. The use of imitation

100 plays an important role during sound approximation strategies (Secord 1981). For approximations to be successful, the strategy of analogy also must be applied. An analogy is a resemblance or comparison in some particulars between things otherwise unlike. Ling (1976) summarized analogies in this statement: Analogies can be auditory, visual, or tactile, depending on the child's sensory capacities and on the

nature of the behavior to be taught. For example, an auditory analogy might be used to show the commonality of nasality in sounds such as m and n, or b and d; a visual analogy, using one hand to represent the palate and the other the tongue, might be used to demonstrate relative points of occlusion for /t/ and /k/; or a tactile analogy, using the fingers on the chin to feel vibration, might be used to indicate that both v and z are voiced. The most effective use of analogy is to show that a sound or behavior that is known shares a particular characteristic with the sound or behavior that is being learned (p. 288). Prompting is another effective strategy used to evoke sounds. Prompting activities involve the association of a particular manner of production with specific objects or actions (Ling 1976). For example, you might touch your chest to cue the student to lower pitch register. This technique should be used when an auditory presentation is unsuccessful and only after the phoneme can be consistently produced. The prompt should be discontinued as soon as possible, since its continued use may impede the development of coarticulation skills (Ling 1976). Vocal play is a recommended strategy for eliciting sounds. Encouraging the child to generate sounds spontaneously in the course of play establishes the use and control of the speech organs (Ling 1976). Once the sound is produced during vocal play, the instructor is challenged to bring the child to a consistent imitation stage. It may be necessary to probe for imitation during vocal play for a substantial time before the child is able to imitate consistently. This strategy is one of the most effective for evoking sounds in young children. Direct verbal instruction is another effective strategy. Instructions must be concise; for example, "Close your lips for /m/" or "I want to see your teeth." This strategy is more successful with older students and adults. Verbal instruction is most effective when combined with imitation and sound approximations. Another strategy used to teach hearing impaired students is explanation of component skills. When using this strategy, first explain to the student what component parts are needed to produce the sound (for example, "I want you to say au. Say a and the u together. Blend them smoothly on one breath"). This strategy is less effective in the

101 early stages of speech acquisition because most hearing impaired children do not have the language to understand the explanation and apply it. However, thoughtful use of this strategy can produce positive results. The final strategy is that of manipulation. This strategy is primarily a tactile strategy with a visual component. Manipulation may be defined as the shaping of a speech behavior through gentle force imposed on one or more of the speech articulators (Ling 1976). The most preferred type of manipulation is that in which the student adjusts the articulators by using a finger or tongue depressor. Manipulation is the last strategy used and is usually not necessary. The strategies of manipulation and tactile imitation are closely associated and are considered by some to be one and the same. Once the student can reliably imitate, manipulation is unnecessary, and some form of auditory or visual cues may be more appropriate.

3.7 Individual and Group teaching: Strengths and Challenges

Individualized Teaching Strategy

Individualized instruction is also known as differentiated instruction. Individualized instruction strategy refers to those classroom practices of teaching which recognize the uniqueness of each student learner and thus provide for adequate tutorial guidance, and other support services suited to bring about a wholesome development in the person (mind, body, and spirit). Individualized instruction is about using teaching strategies that connect with individual student's learning strategies. The ultimate goal is to provide a learning environment that will maximize the potential for student success. In this strategy the teacher shouldn't always stick to the same pattern of teaching rather they should adapt new ways such as teaching through audio, video, field trip, etc. so that students have multiple options for taking in information and making sense of ideas. The intent of individualizing instruction is to maximize each student's growth and individual success by meeting each student where he or she is, and assisting in the learning process. It provides the opportunity for students to learn at their own pace, in their own way, and be successful.

Advantages and disadvantages of Individualized instruction strategy.

Advantages: 1. Student-Centric Differentiated instruction focuses on the academic needs and learning abilities of every individual student. By changing the methods of teaching to suit students,

102 teachers are able to adjust the content of the syllabus. This encourages critical thinking in students, and gives them a chance to come forward and demonstrate what they have learned. It also creates a sense of equality among students, including the ones with a learning disability. Differentiated learning provides ample opportunity for students to aim and attain academic success with aplomb. 2. Raises The Bar Advocates of this teaching approach believe differentiated learning raises the standards of learning in a big way. The true essence of this practice lies in the realization that learners and their abilities, readiness and interests vary. Educators have the liberty to set up classrooms and devise methods that would aid all students in thinking, analyzing and comprehending the teaching contents easily. Differentiation does not have hard and fast rules; it is all about options. 3. Meeting the needs and interests of diverse learners. 4. Provides the opportunity for students to learn at their own pace, in their own way, and be successful. 5. Recognizes students' varying background knowledge, readiness, language, preferences in learning, interests, and to react responsively. 6. Maximizes each student's growth and individual success by meeting each student where he or she is, and assisting in the learning process. 7. Helps in providing for the uniqueness of each child in terms of his/her particular learning style, talents and potential, handicaps and deficiencies, etc. Disadvantages: 1. Time constraints and chopped-up schedules are an obstacle. Teachers could work better if they had longer blocks of time with students. At the elementary level, kids have to go somewhere or someone comes in to do something every 15-30 minutes; at the secondary level, kids rotate in and out every 37 or 42 minutes. It makes teachers crazy. 2. Class size and teaching load are two of the biggest constraints. A teacher who works with 150 kids a day gets glassy-eyed when told he needs to get to know those kids better. It's doable, but we would be far more efficient by arranging schedules so teachers had fewer students to get to know or kept them over longer periods of time.

103 3. Teacher Preparedness. Sometimes, the teacher's lack of adequate knowledge on individualizing instruction could also serve as a serious obstacle in individualizing instruction in the classroom. The teacher's lack of knowledge and ignorance could be further aggravated when the school does not have the essential resources to support individualized or differentiated instruction. GROUP TEACHING Using Group Work and teamwork. Co-operative learning involves having students work together to maximize their own and one another's learning (Johnson, Johnson & Smith, 1991). Team teaching involves a group of instructors working purposefully, regularly, and cooperatively to help a group of students of any age learn. Teachers together set goals for a course, design a syllabus, prepare individual lesson plans, teach students, and evaluate the results. They share insights, argue with one another, and perhaps even challenge students to decide which approach is better. Teams can be single-discipline, interdisciplinary, or school-within-a-school teams that meet with a common set of students over an extended period of time. The team-teaching approach allows for more interaction between teachers and students. Faculty evaluate students on their achievement of the learning goals; students evaluate faculty members on their teaching proficiency. Emphasis is on student and faculty growth, balancing initiative and shared responsibility, specialization and broadening horizons, the clear and interesting presentation of content and student development, democratic participation and common expectations, and cognitive, affective, and behavioral outcomes. This combination of analysis, synthesis, critical thinking, and practical applications can be done on all levels of education, from kindergarten through graduate school. Working as a team, teachers model respect for differences, interdependence, and conflict-resolution skills. Team members together set the course goals and content, select common materials such as texts and films, and develop tests and final examinations for all students. They set the sequence of topics and supplemental materials. They also give their own interpretations of the materials and use their own teaching styles. The greater the agreement on common objectives and interests, the more likely that teaching will be interdependent and coordinated. Teaching periods can be scheduled side by side or consecutively. For example, teachers of two similar classes may team up during the same or adjacent periods so that each teacher may focus on that phase of the course that he or she can best

104 handle. Students can sometimes meet all together, sometimes in small groups supervised by individual teachers or teaching assistants, or they can work singly or together on projects in the library, laboratory, or fieldwork. Teachers can be at different sites, linked by video-conferencing, satellites, or the Internet. Breaking out of the taken-for-granted single-subject, single-course, single-teacher pattern encourages other innovations and experiments. For example, students can be split along or across lines of sex, age, culture, or other interests, then recombined to stimulate reflection. Remedial programs and honors sections provide other attractive opportunities to make available appropriate and effective curricula for students with special needs or interests. They can address different study skills and learning techniques. Team teaching can also offset the danger of imposing ideas, values, and mindsets on minorities or less powerful ethnic groups. Teachers of different backgrounds can culturally enrich one another and students. Advantages

Students do not all learn at the same rate. Periods of equal length are not appropriate for all learning situations. Educators are no longer dealing primarily with top-down transmission of the tried and true by the mature and experienced teacher to the young, immature, and inexperienced pupil in the single-subject classroom. Schools are moving toward the inclusion of another whole dimension of learning: the lateral transmission to every sentient member of society of what has just been discovered, invented, created, manufactured, or marketed. For this, team members with different areas of expertise are invaluable. Of course, team teaching is not the only answer to all problems plaguing teachers, students, and administrators. It requires planning, skilled management, willingness to risk change and even failure, humility, open-mindedness, imagination, and creativity. But the results are worth it. Teamwork improves the quality of teaching as various experts approach the same topic from different angles: theory and practice, past and present, different genders or ethnic backgrounds. Teacher strengths are combined and weaknesses are remedied. Poor teachers can be observed, critiqued, and improved by the other team members in a nonthreatening, supportive context. The evaluation done by a team of teachers will be more insightful and balanced than the introspection and self-evaluation of an individual teacher. Working in teams spreads responsibility, encourages creativity, deepens friendships, and builds community among teachers. Teachers complement one another. They

105 share insights, propose new approaches, and challenge assumptions. They learn new perspectives and insights, techniques and values from watching one another. Students enter into conversations between them as they debate, disagree with premises or conclusions, raise new questions, and point out consequences. Contrasting viewpoints encourage more active class participation and independent thinking from students, especially if there is team balance for gender, race, culture, and age. Team teaching is particularly effective with older and underprepared students when it moves beyond communicating facts to tap into their life experience. The team cuts teaching burdens and boosts morale. The presence of another teacher reduces student-teacher personality problems. In an emergency one team member can attend to the problem while the class goes on. Sharing in decision-making bolsters self-confidence. As teachers see the quality of teaching and learning improve, their self-esteem and happiness grow. This aids in recruiting and keeping faculty. Disadvantages Team teaching is not always successful. Some teachers are rigid personality types or may be wedded to a single method. Some simply dislike the other teachers on the team. Some do not want to risk humiliation and discouragement at possible failures. Some fear they will be expected to do more work for the same salary. Others are unwilling to share the spotlight or their pet ideas or to lose total control. Team teaching makes more demands on time and energy. Members must arrange mutually agreeable times for planning and evaluation. Discussions can be draining and group decisions take longer. Rethinking the courses to accommodate the team-teaching method is often inconvenient. Opposition may also come from students, parents, and administrators who may resist change of any sort. Some students flourish in a highly structured environment that favors repetition. Some are confused by conflicting opinions. Too much variety may hinder habit formation. Salaries may have to reflect the additional responsibilities undertaken by team members. Team leaders may need some form of bonus. Such costs could be met by enlarging some class sizes. Nonprofessional staff members could take over some responsibilities. All things being considered, team teaching so enhances the quality of learning that it is sure to spread widely in the future.

109 for helping children with hearing loss acquire language and communication skills. The most common approaches are: (a) auditory- oral (AO); (b) auditory-verbal therapy (A VT); (c) total communication; and (d) the bilingual-bicultural approach. AO and A VT approaches are similar in that both aim to assist children develop spoken language and enable full integration into mainstream society. Both promote early diagnosis of hearing loss, followed by immediate and optimal amplification. They place an emphasis on the consistent use of hearing technology. However, they differ in that the AO approach encourages the use of lip-reading, facial expression, and naturally occurring gestures. A VT, on the other hand, de-emphasizes the use of visual cues (Estabrooks, 2006). Total communication is a multisensory approach which is practiced widely around the world. It aims to offer the most appropriate oral and visual codes according to individual needs (Lynas, 1999). The signing in total communication is a contrived sign system (e.g. Signed English) that was designed to be used simultaneously with a spoken language. It is not a natural sign language (Lynas, 2005). A natural sign language, such as the Indian Sign Language is one that has evolved within a Deaf community and has its own unique grammar and word order. In recent years, some early intervention centers have moved towards the use of natural sign languages as part of bilingual-bicultural education, which involves teaching a natural sign language as the child's first language and spoken/written English as their second language.

4.2. Objectives The objectives are: 1. To familiarize the reader with the types of communication options available for teaching language to the hearing impaired child. 2. To justify the use of different communication options across different educational setups. 3. To describe the strengths and weaknesses of each communication option.

4.3. Methods of Teaching Language: Natural, Structural and Combined Communication is the process of exchanging information and ideas. An active process, it involves encoding, transmitting, and decoding the intended message. Each communication partner must be alert to the needs of the other, so that messages are

110 conveyed effectively and intended meanings preserved. Speech and language are only a portion of communication. Other aspects of communication may enhance or even eclipse the linguistic code. These aspects are paralinguistic, nonlinguistic, and metalinguistic. The child communicates from the time of birth. Early communication does not depend on the use of language or speech. In fact, communication provides the vehicle within which initial language develops. As language improves, there is also a corresponding improvement in overall communication abilities. Education of Children with Hearing Impairment: "Education is not an advantage, but a basic right of every individual's life". Educational aims are based on the life and needs of individuals. However, few percentage of children due to their disability have difficulty in meeting their needs through general education, these children have special educational needs apart from ordinary needs and require special attention and training in satisfying their needs. Aims of Special Education: Primary aim of education is to provide opportunities for the individual to develop the innate capacities, learns to make adjustment, improve speech and language development. Maximize use of residual hearing Improve IQ Improve social adjustment and behavior Improve cognitive skill Stimulate thinking and memory Teaching methods: 1) structured method 2) natural method 3) combined method Structured method: - Structured method believes that language is teachable hence has to be taught. It advocates the use of symbol system to represent the structure. Students are made to work on grammar rules by analyzing, categorizing the grammatical aspects. It advocates the use of memorization and imitation work in developing patterns of language.

111 Natural method: - Believes that language is not teachable - it is learned. One has to ensure exposure and input and the children "learn" the language naturally.

Child is expected to acquire language implicitly through interaction occurring within the environment. No symbol system is

used. The main emphasis is on the development of language via oral conversation method based on the experience of the children as it happens naturally in the home environment and the instructions are all planned to parallel the sequence of language acquisition in hearing children.

Combined method: - Utilizes components of both structured and natural method.

4.4. Principles and Techniques of Developing Language: Language development in hearing impaired children: - The degree and type of hearing loss has distinct impact on development of speech and language in hearing impaired children. According to Sharma and Jangira (1987), language development and speech is mildly affected in moderate hearing-impaired children.

Difficulty with rarely used words, minor differences in meaning of words and idioms,

reading and writing are delayed. In the case of children with moderately severe hearing loss, grammar, vocabulary, articulation and voice are affected. Severe hearing impaired children's speech and language may not develop spontaneously. Their voice is usually high-pitched and articulation is distorted. Profound hearing impairment children's speech and language are severely affected. Language for preschool hearing impaired child: - The Oral method and Sign Language are the two most widely used and highly debated methods of communication for the deaf. Some believe the Oral communication method to be most beneficial for deaf individuals while some agree on Sign Language to be the most beneficial method. The root of the debate lies in the fact that the method of communication used can affect the social and educational aspects of a deaf individual's life. Further, the basis of this debate stems from differences in personal preferences which have been affected by historical influences. It is in this debate that parents, teachers, deaf students, deaf adults, and all involved can make a communication decision based on the values and benefits each method entails.

112 4.5. Communication Options: Compare and Contrast ORALISM: - The concept of Oralism has existed since the time of the great philosopher Aristotle. However, Oralism only became widely used and accepted in the mid-1500's when a Spanish monk, Ponce de Leon, began to educate deaf students through Oral communication for religious purposes. From there, the development of Oralism continued throughout the centuries, changing and advancing in instruction until it was commonplace for a deaf individual to solely listen and speak. Oralism won out as the top communication method used for deaf individuals in America until a decrease in use in the 1970's and 1980's. Prerequisites for adopting Oralism Provision of appropriate amplification As soon as the infant or child is diagnosed as deaf, it is considered crucially important to fit appropriate hearing aids. Without hearing aids the child with a severe or profound hearing loss will have little or no access to the sounds of speech. The hearing aids must be carefully prescribed in order to take into account the nature of the child's hearing loss and amplification needs. Hearing aids must also be carefully maintained so that they perform as intended. Parents, in the first place, must take responsibility for keeping the hearing aids in good working order and for ensuring that they are correctly placed in the ears. Research has demonstrated that there is a significant correlation between speech achievements and good use of hearing aids (Ling and Ling, 1978). So despite the difficulties involved, oralists emphasize the need for good hearing aid use. The current oralist emphasis on the exploitation of residual hearing through hearing aids does not imply that visual information plays no part in the perception of speech and the understanding of spoken communication. Where there is hearing impairment the auditory sense will, so most oralists believe, be supported by visual communication such as facial expression, lip movements, body language, and natural gestures. Spoken language experience:- Oralists have spent a considerable amount of time thinking about how to provide the right kind of language experience during the deaf child's developing years (Nolan and Tucker, 1988; Clark, 1989). Modern oralists take the view that it is very important that the spoken language surrounding the hearing impaired child is relevant to his or her needs and interests. The language offered should be related to the child's focus

113 of attention at any particular moment. Creating situations which require communicative exchange is part of the skill required by an adult in facilitating language acquisition. Once adults develop sensitivity to the deaf child's interests and communication needs, satisfying interaction can occur (Clark, 1989). The more the adult offers communication that is relevant to the deaf child's interests, the more the child will attend to speech and the more responsive and interactive he becomes. Communicating with the hearing impaired child gets progressively easier for the adult. And, as these children develop their capacity to listen, the more feedback they get from their own vocalizations and this in itself encourages further vocalization. As the auditory signals received by the child from the spoken language environment come to be perceived as linguistic symbols so the process of language acquisition gets under way. Support for Oralism: - Those who believe in Oralism as the most beneficial communication method do so because of the benefits it offers for deaf individuals for assimilation into a hearing society and in education. Oralists choose these benefits over those provided by ASL as they are based on personal fundamental values for what they see as most necessary in life. These values that Oralists embrace come from the historical influences of educational endeavors and conformity to social norms. The Oral communication method does indeed procure higher levels of educational success and assimilation into the hearing society for deaf individuals. Current research indicates that deaf individuals using Oralism, compared to their deaf non-oral peers, tend to have higher vocabulary, literacy rates, and opportunities. Deaf individuals who use Oralism have proficiency with spoken language and have an average reading ability of thirteen to fourteen-year-old levels, which is approximately double the US national average for all children who are deaf. Furthermore, programs using Oralism generally have strong academic curricula resulting in high achievement levels and more students who go on to complete secondary or higher education programs. This also results in more social, educational, and work opportunities and to a more fulfilling and independent adult lifestyle. These benefits of Oralism allow deaf individuals to reap the educational benefits and equal opportunities that the Oralists, continue to cherish.

114 Furthermore, the Oral communication method also has new strategies and technology to assist in successfully educating the deaf. According to ASL Access, which is a leading organization providing media to deaf individuals, those who use the Oral method have more qualified teachers. Deaf individuals using other communication methods often lack qualified and fluent teachers as most teachers of the deaf are hearing adults. On the other hand, deaf individuals using Oralism have a consistent and a plentiful supply of role-models who understand their primary language and how to teach with it. Also, there are laws that ensure educational supplements or services are available to provide the proper aid and instruction necessary for the deaf individuals. This includes necessary services such as speech therapy, audiology services, and special education teachers to ensure educational success through Oralism. Also, the development of new technology has allowed for more deaf individuals to access oral communication, which in turn allows for easier access to educational information. The recent developments in technology include cochlear implants, hearing aids, FM Systems, and several other devices that enhance the ability of deaf individuals to use their residual hearing. All of these developments assist deaf individuals in using Oralism to facilitate easier education. Because of the benefits received from the use of Oralism, increasing access to it, and the importance placed on education by Oralists, it is seen that the Oral communication method can indeed be beneficial to deaf individuals. Apart from education benefits, assimilation into the hearing community is another advantage of oralism. The benefits for the assimilation of deaf individuals are two-fold. First, deaf individuals benefit from it because they become included and accepted by the majority, the hearing population. Deaf individuals using a communication method other than Oralism have been less accepted in schools and in the workplace because it was evident that they were different from norm. Using Oralism to assimilate deaf individuals into the majority allows them to feel accepted, which is a noted fundamental value of Oralists.

115 The second benefit of assimilation of the deaf is the ease it provides to the hearing majority during communication. Deaf individuals using Oralism can generally integrate into work and social areas because of their ability to "appear" assimilated into the social norms and therefore make communication for all less intimidating. Thus, it is clear that the Oral communication method provides benefits both in education and assimilation and, because of their fundamental values; Oralists declare it as the most beneficial communication method for deaf individuals. Problems with Oralism 1. Language Delay Oralists acknowledge that with an auditory-oral approach profoundly deaf children typically do not learn to listen immediately they are fitted with hearing aids and that spoken language acquisition takes longer than when a child has normal hearing or a less severe hearing loss (Nolan and Tucker, 1988; Clark, 1989). Delay in language acquisition does mean that some deaf children cannot communicate through language during the early years in quite the same way as a hearing child. The frustration caused by this delay make deaf children suffer serious emotional problems which may persist into adulthood (Meadow, 1980). Also, there may be a problem when the language-delayed deaf child starts school. 2. The Struggle to Communicate and Acquire Language The hearing impaired child is always at a disadvantage relative to hearing children in receiving information via the spoken word: the hearing impaired child must concentrate harder with both eyes and ears to keep abreast of lesson material. Furthermore, to be obliged to communicate throughout the day through spoken language increases the burden. This is particularly so for the mainstreamed hearing impaired child who is surrounded by competent hearer-speakers and who is likely to be reminded frequently of his hearing handicap by failures to grasp what is being said and by an inability to participate fully in the informal school life. 3. Suppression of Deaf Identity An oral education implies that the hearing impaired child should assimilate into the hearing world and become 'normalised'. The hearing impaired child is 116 required to conform as far as possible to the norms of hearing society and this is a violation of justice. An oral education in the mainstream denies deafness and implies an attempt to make a deaf child be what he or she can never be: a hearing person (Merrill, 1981). 4. Persistence of Oral 'Failure' Some writers think that there are differences in children's psychoperceptual abilities and that when a child is very deaf this feature can have a crucial influence on ability of some children to make use of residual hearing (Bamford and Saunders, 1991). Tumin (1982), on the basis of her experience with her two hearing handicapped believes that the ability to perceive the prosodic features of the speech is a crucial factor. The daughter, who acquired spoken language easily, was having a more severe loss than her sister but could perceive the intonational patterns of speech, whereas her sister could not. Oral 'failure' has considerably reduced over the last 10-15 years and oralists believe that some of the current 'failure' is a consequence not of the auditory-oral approach per se but of poor implementation of that approach. Most oralists would argue, anyway, that all children, however deaf, should be given the chance to develop oral language through a natural auditory approach since we do not know in the early stages how well a child can hear or perceive speech. 5. The Need for Perfect Conditions There is a view which accepts that fluent spoken language is a desirable goal and that many hearing impaired children have the potential to achieve it but that in practice the goal is only achievable under certain conditions. These conditions, it is argued, are often too difficult to meet. According to this view the demands of the auditory-oral approach, with the necessity for consistently good hearing aid maintenance and management and the need for a facilitating oral language environment both at home and at school, are beyond the capacity of parents and educators. However, researchers like Clark (1989) claimed that there have been good oral achievements for many deaf children and young people despite a combination of unfavourable factors. This is not to be said that the presence or otherwise of these features and circumstances have no significance but that they are not, as it is claimed, crucial factors.

117 SIGN LANGUAGE: - In the late 1700's and 1800's, sign language emerged as a communication method for the deaf and was used extensively. In USA, it was not until the 1800's that ASL was introduced to deaf individuals as an official communication mode. Sign language was brought to America in 1817 by Thomas Hopkins Gallaudet, an American clergyman in search of a new method of deaf education, and Laurent Clerc, a deaf Frenchman who used signed communication. Together the two men configured the beginnings of a signed language and established the first deaf school in America that led to the development of American Sign Language. Sign language is a visual language with its own grammar that uses manual movements to represent concepts (Schirmer.A. 1993). Some people consider sign language to be the natural language of deaf individuals because they use visual and tactile input to compensate for the loss of auditory input. Sign language is an independent language and has complex structures like any other verbal language. The structure of any sign language like ISL, ASL, BSL etc. is not the same like any verbal language. Sign languages change country to country and are not universal. There exists many numbers of sign languages. Sign languages are not man made. It has evolved on its own like any natural language. Like verbal languages, sign language too has regional variety, for example, Hindi of a Delhite and the Hindi of Mumbaian are very different. India too has assigned language with its regional varieties. Sign languages have its own dictionary and grammar. The characteristics of a language displacement, arbitrariness, cultural transmission, creativity, and duality are present in sign languages. Sign languages do not only involve use of 'only hands'. Hands play a very significant role in sign language, whole body and facial expressions too have a part in sign language. The features of a sign language are: Designator - the hand shape Tabula - the location of the sign Signation - hand movement of the sign Orientation - the direction of the movement relative to the signer's body. There are differences between sign language and sign system. They are:

118 Sign Language Sign System Each concept/word has a sign Each morpheme has a manual sign Naturally evolved Artificially made Has independent grammar Uses grammar of the verbal language Has to be used independently Has to be used along with speech Supposed to replace speech Supposed to supplement speech Used in bilingualism Used in Total Communication Indian Sign Language Indian sign language is not well studied or adequately documented. Hence many of its aspects related to grammar and its use in the deaf society remain unknown. Sign language is an integral part of the deaf community in India. ISL is used by over 10, 00, 000 deaf adults and approximately 500,000 deaf children (Vasistha et al., 1980) less than 5% of whom attend special schools for deaf students. While there are 15 official languages in India and over 200 different dialects, there is only one Indian sign language. There are four major regional dialects centered in the urban areas: Delhi (North), Kolkata (East), Bangalore-Chennai (East) and Mumbai (West). It is claimed that ISL is used not only on India but also in Pakistan (Zeshan, 2000). ISL has various regional varieties sharing the same grammar. Zeshan claims that common vocabulary among the regional varieties is from 60% - 85%. Indian Sign System In western developed countries one verbal language has several parallel sign systems created by different scholars. For example, English has many parallel sign systems like Seeing Essential English (SEE I), Signing Exact English (SEE II), Signed English (SE), Sign English (SE) etc. verbal languages in India do not have as many parallel sign systems as in English. However, due to a UNICEF funded project at A YJNIIH, Indian sign systems have been created. These are created keeping the vocabulary and grammar of the language in mind. ISS, like any other sign system, has to be used with speech. Support for Sign Language: - There is still the side of the debate supported by sign language groups who do

119 not disvalue education and assimilation, but instead highly value social-emotional benefits and the privilege to exercise human rights. Developing social-emotional stability is one way to be at peace with oneself. Aspects such as an individual who can adequately function, hold positive self-esteem, and accept oneself are some examples of sound social-emotional development. These aspects are known to be procured through using sign language, which is why those who support strong social-emotional development also promote sign language. Current research suggests that, deaf individuals who use sign language as a communication method have indeed been found to have higher social-emotional development than those deaf individuals who do not. The deaf individuals who use sign language have higher self-esteem, feel valued, feel complete and not "broken", and have a strong sense of identity so they can feel accepted for who they are and not for what others want them to be (Orsi 1, Sign Media, Inc. 2). They also identify more readily with their deafness and are confident in themselves as a whole individual whereas those who use Oralism find themselves in denial of deafness, "fixed," forced to speak so they are more "normal," and devalued by society. Furthermore, deaf sign language users receive additional social-emotional development because they can identify with a community of people that shares sign language as a communication method, the Deaf Culture. Furthermore, deaf sign language users receive additional social-emotional development because they can identify with a community of people that shares sign language as a communication method, the Deaf Culture. The Deaf Community is a community that not only shares the communication method of sign language, but also shares a culture that gives acceptance to deaf individuals for who they are despite their "differences". Although this acceptance does come from a minority group, it comes wholeheartedly as conformity nor is educational status necessary. Belonging to the Deaf Culture allows deaf individuals to be proud of being deaf and form a stable and true sense of identity (Schirmer 1994). In the Deaf

120 Culture it is understood that deafness is not a disability but instead it is an accepted and respected characteristic. There is still the side of the debate supported by sign language groups who do not disvalue education and assimilation, but instead highly value social-emotional benefits and the privilege to exercise human rights. Developing social-emotional stability is one way to be at peace with oneself. Aspects such as an individual who can adequately function, hold positive self-esteem, and accept oneself are some examples of sound social-emotional development. These aspects are known to be procured through using sign language, which is why those who support strong social-emotional development also promote sign language. Current research suggests that, deaf individuals who use sign language as a communication method have indeed been found to have higher social-emotional development than those deaf individuals who do not. The deaf individuals who use sign language have higher self-esteem, feel valued, feel complete and not "broken", and have a strong sense of identity so they can feel accepted for who they are and not for what others want them to be (Orsi 1, Sign Media, Inc. 2). They also identify more readily with their deafness and are confident in themselves as a whole individual whereas those who use Oralism find themselves in denial of deafness, "fixed," forced to speak so they are more "normal," and devalued by society. Furthermore, deaf sign language users receive additional social-emotional development because they can identify with a community of people that shares sign language as a communication method, the Deaf Culture. Furthermore, deaf sign language users receive additional social-emotional development because they can identify with a community of people that shares sign language as a communication method, the Deaf Culture. The Deaf Community is a community that not only shares the communication method of sign language, but also shares a culture that gives acceptance to deaf individuals for who they are despite their "differences". Although this acceptance does come from a minority group, it comes whole-

121 heartedly as conformity nor is educational status necessary. Belonging to the Deaf Culture allows deaf individuals to be proud of being deaf and form a stable and true sense of identity (Schirmer 1994). In the Deaf Culture it is understood that deafness is not a disability but instead it is an accepted and respected characteristic. In addition, using sign language as a communication method allows for equal interactions among deaf individuals within the Deaf Community. Conversing with other deaf individuals who share the same concerns, language, deaf pride, confidence, and self-esteem is invigorating and encouraging. Thus, using sign language and belonging to the Deaf Culture has proven to be beneficial for deaf individuals' social-emotional development. In addition to social-emotional development to promote inner peace, using sign language as a communication method also allows deaf individuals to exercise human rights. Thus, it is reasonable to understand how the social-emotional benefits and use of sign language as a communication method fulfill these fundamental values of sign language groups who then label Sign Language as the most beneficial communication method for deaf individuals.

Problems with Sign Language

1. Sign language and parents of the deaf: Parents feel a time pressure to learn and be proficient in sign language. The communication, many times, is restricted to the parent's skill in sign language usage.
2. Access to the Curriculum through Sign Language The majorities of teachers of the deaf currently working are 'hearing' and have not received training in sign language. Moreover, the sign language does not incorporate the conventions of everyday colloquial language. There is also problem in semantic distortion in the use of Idiom through sign language.

THE BILINGUAL APPROACH Bilingualism is a relatively new idea and one which has attracted a lot of recent attention and interest. Bilingualism can be seen as a reaction against both oral-only and TC approaches. Bilingualists share with advocates of Total Communication (TC) the view that an auditory-oral approach fails to meet the communication and linguistic needs of children with substantial hearing losses. But bilingualists are equally critical of TC and agree with the view that combining speech with a contrived system of signs does not bring verbal language to deaf children. Furthermore, they believe that TC does not directly offer a language in sign. TC is perceived to be speech centred and speech does not serve the developing deaf child's communication and language needs. The introduction of TC has been successful in persuading many former oralists to become more 'flexible' in their attitude towards sign and prepared to acknowledge that an oral-only approach does not meet the needs of at least some deaf children. It is suggested that sign is the natural language of the deaf: their 'biologically preferred' mode (Charrow, 1975). Young deaf children, left to communicate among themselves, have been observed 'naturally' to develop a gestural code of communication (Heider and Heider, 1941). Thus, fundamental to the bilingual approach is that the first language of all deaf children should be the sign language which belongs to the Deaf community of the country concerned. Bilingualists consider access to sign language, as a first language, is the birthright of all deaf children. However, there is support for bilingualism and acknowledgement of the deaf child's need for verbal language. Literacy is an important goal for bilingualists because they accept that without the ability to read and write an individual is handicapped in a society. However, for bilingualists the route to verbal language is different from that advocated by supporters of oralism or TC. There appears to be universal advocacy of learning verbal language as a second language. A verbal language, such as English, should be taught only when the first language, sign language, has become established in the developing deaf child. With both oralism and TC the aim is that the verbal language (e.g. English) should be acquired as a first language.

Components of Bilingual Approach? Strategies for the Acquisition of Sign Language: the Preschool Years

1. In the first few months of the deaf infant's life the baby is much preoccupied with the touch, smell and sight of the care-giver and at this stage deaf mothers tend to vocalise more than they sign (Woll and Kyle, 1989).
2. It is when the infant sits up independently and pays attention to aspects of the wider environment that the signing parent starts to communicate in sign. The signing care-giver must gain the deaf infant's visual attention to give information through sign yet at the same time relate the information to the object, or focus

123 of attention in the environment. 3. Signing care-givers adopt a variety of strategies to overcome the problem of divided attention. Care-givers manoeuvre themselves into the visual field of the infant and produce a high proportion of signs within the child's focus (Harris et al., 1989). Care-givers wait for the deaf child to look at them and then produce signs appropriate to the situation (Mills and Coerts, 1990). It is possible to get the child first to attend to the care-giver's face by gently tapping the child, or moving his or her face, and then sign what is to be referred to while pointing the (care-giver's) arm in the direction of the object (Woll and Kyle, 1989). A care-giver can point to an object, or picture of an object, checking that the child's gaze is directed towards the object or picture and then redirect the child to the adult and provide a sign for that object (Woll and Kyle, 1989). Another strategy observed is to sign on the deaf infant's body (Maestas and Moores, 1980) and to manipulate the child's hands into the shape of signs and guide its movements (Bouvet, 1990). Ensuring that the deaf child is seated comfortably and is supported means that the adult can face the child and at the same time look at pictures or play with toys. In this situation an adult can offer signs without being physically separated from the child (Mills and Coerts, 1990). Learning through Sign: The School Years 1. It is assumed that by the time the deaf child reaches school age he or she has achieved the linguistic competence necessary to have access to the normal school curriculum (Johnson, Liddell and Erting, 1989). Following the bilingual principle of using the child's first language for educational purposes the curriculum should be offered in sign language. Those who offer curricular content to the children must be fluent signers. For this to be achieved it is extremely important, to make considerably more use of deaf signing adults in formal education than is currently the case (Pickersgill, 1990). 2. It is Sign Language, as the L 1 of deaf children, which should be used to enable the child to acquire L2, such as English. According to Johnson, Liddell and Erting (1989), verbal language will be taught as a second language and methods of verbal language instruction will take advantage of the first language competence the children already have. Amongst bilingualists there now seems to be almost universal approval of approaching verbal language via the written rather than the spoken form (Johnson, Liddell and Erting, 1989). The reason

124 for not approaching verbal language through speech is the belief that essentially deaf people perceive language in a visual and not in an auditory way. It is important, therefore, that as part of this process deaf children are enabled to come to an understanding of the linguistic principles of sign language, of the way it is structured and formed. Bilingual Approach: Pros and Cons One problem with attempting to evaluate the efficacy of a bilingual approach is that we do not have sufficient experience of use of the approach to know whether or not deaf young people emerge from it as fluent signers and as literate, knowledgeable and well informed people. The main elements of the argument seem to be these: 1. Deaf people should be recognised not as handicapped individuals but as a cultural and linguistic minority group with rights of access to education, employment, etc. equal to those of other members of society. 2. Natural sign languages have the same linguistic status as verbal languages. 3. Deaf children have the right to acquire their own 'indigenous' language, sign language, as a first language. 4. Given appropriate experience, deaf children acquire sign language at the same rate and in a manner that is very similar to the way hearing children acquire spoken language. 5. Hearing parents, if offered appropriate support, can communicate comfortably through sign with their young deaf child. 6. Deaf signing adults have an important role to play in helping hearing parents acquire sign communication and in developing sign language in deaf children. 7. Deaf children should be educated through the medium of sign language as only then will they have full access to the normal school curriculum. 8. Deaf children can become literate, that is, acquire verbal language in the written form through the language base of natural sign language. 9. It is morally wrong to impose on deaf children a language they cannot apprehend, that is, spoken language. 10. The linguistic potential of the deaf child can be realised only through being enabled to acquire sign language as a first language.

125 Communication Strategy for High School going Hearing impaired Communication training is instruction provided to a person with hearing loss to maximize his or her communication potential. A communication strategy is a course of action taken to facilitate a conversational interaction or to rectify a problem that arises during conversation. It include any verbal or non verbal behaviors that can be used to improve the effectiveness of communication (Gagne et al 1991). Tye murray (1994) grouped communication strategies under two general categories. a) Facilitation strategies b) Repair strategies. (a) Facilitative strategies This includes instructing the talker and structuring g the listening environment to enhance the listener performance. There are four Facilitative strategies, which may be used to influence: i) Communication environment:- Constructive strategies are managing the physical environment In which conversation takes place. (eg noise poor lighting). A person structures the environment to optimize communication by minimizing background noise and ensuring a favorable view of the talker. e.g, move close to talker, reduce background noise, adequate lighting, no reverberation in room etc. ii) Patients speech recognition skills: Adaptive strategies:- The individual with hearing loss implements relaxation techniques. Attending strategies:- the individual pays attention to situational, linguistic and facial cues for the purpose of inferring partially recognized messages (e.g. anxious / happy) Both adaptive and attending strategies are methods of counteracting maladaptive behaviors that stem from hearing loss. Anticipatory strategies:- The individual prepares for conversation interaction In advance by anticipating conversational content and potential listening difficulties. iii) Communication partner Instructional strategies: A person influences the 126 communication partners speaking behaviors by asking the partner to speak clearly, facing forward. iv) Message:- Message tailoring strategies: Individuals encourage communication partners to use short sentences or they control the topic of conversation. Erber (1988) had shown that persons with HL have less difficulty answering questions that require a closed set response than general open ended question. (b) Repair strategies Repair strategies are behaviors used to overcome a communication breakdown between communication partners. A communication breakdown occurs when one of the communication partners fails to understand-a message that was intended for that person (Gagne et al 1991) Repair strategies can be used by the person who is providing the information (expressive strategies) or by the person for whom the message is intended (receptive strategies) Receptive strategies: Could you say that again (Repeat repair strategy). Who is going to give you ride (Request for information repair strategy). I missed that completely that (key word repair strategy) are you talking about? Asking for more information (elaborate repair strategy). Expressive repair strategy:- are used to rectify the communication breakdown that occurs because the HI person produces an unintelligible speech utterance, and conversational partner cannot recognize it) Specific repair strategies: Repeat all or part of message Rephrases message Elaborate message Simplify the message Indicate the topic of conversation Confirm the message 127 Write Finger spell. Non specific repair strategies: What Huh Pardon Model for communication training: The model provides a frame work for stages of communication strategies training (Tye Murray 1992) 1. Formal Instruction 2. Guided learning 3. Real world practice. Formal instruction:- Provides individuals with information about vanous types of communication strategies and appropriate listening and speaking behaviors. Guided learning:- Train the patients to use a communication strategies in a structured setting. Activities include role playing, analysis of video taped scenarios ,continuous discourse tracking and drill activities. Video taped scenarios provide examples of communication interaction that can be used to discuss communication strategies. Individuals view videotaped scenarios that contrast inappropriate with appropriate use of communication strategies. Continuous discourse tracking is another means to provide guided learning. It is an aural rehabilitation technique in which the listener attempts to repeat verbaton text presented by a reader. If, the receiver cannot recognize then he/ she should use a repair strategy. Exercise drills can provide guided learning. An example of a drill activity is a sentence identification task (Tye Murray 1997). Real world practice" practice a new skill or behavior in an everyday environment. Short term training: WATCH (formal instruction) is an acronym that Montgomery (1994) coined to describe

128 short communication strategies training program. W - Watch the talkers mouth not his eye A - Ask specific questions T - Talk about your hearing loss C - Change the situation H - acquire health care knowledge SPEECH (Formal Instruction) S = spotlight your face Keep face visible, distance, same room P = pause slightly while speaking Moderate rate E = empathize and be patient Be patient, utilize facilitative and repair strategies. E = ease their listening Gain listener attention, ask for communication solutions C = control the circumstances Manage environment H = have a plan Use appropriate communication strategies for situations Assertiveness training Most of the time assertive behavior is appropriate for good communication assertive people respect their communication partners, but they also meet their own needs they admit their problems and ask for assistance. The assertive person indicates for e.g. The need to speech read because of poor hearing The difficulty created by the poor lighting. One area that is often addressed in aural rehabilitation is development of assertiveness Behaviors stressed in Assertive training According to Spitzor, Loder and Giolas (1987) some of the behaviors given emphasis

129 In assertive training are 1) Asking for assistance when something is missed e.g. I missed the date of meeting when will the meeting be the place? 2) Getting feedback regarding a portion of the utterance (e.g. I know that you were discussing the movie you saw was the movie Raiders of the Lost Heart?) 3) Information others of hearing impairment 4) Moving seat to advantageous location. 5) Continuing to try to understand (eye contact using communicative repair strategies etc) 6) Attempting to anticipate to flow of conversation 7) Modifying strategy when initial approach is unsuccessful ego (I am sorry but I still don't understand that name would you mind telling a word it rhymes with?) 8) Negative behaviors should be reduced or extinguished. The hearing impaired person should not demonstrate impatience, tension or hostility when there is a communicative failure. Once the behaviors stressed in assertive training are acquired by a hearing impaired person. He/she is ready to select the appropriate strategy depending on the situation and use them effectively. Role playing Discussions are not sufficient in assertiveness training. Clients need an opportunity to practice new skills in a safe structured environment if they are to change a life long history of passive communication behaviors. Role playing in a group can provide practice of new assertiveness skills.

4.6 Communication Option: Justification and Challenges
Communication options for cochlear implanted children: In addition to educational setting, the other major educational decision made relates to communication mode. Oral communication has often been linked with improved outcomes from implantation and that spoken language at an elementary level evidenced

130 higher levels of language and literacy at high school. Studies comparing outcomes from implantation in children using oral communication and those using signed communication often suggest that communication choice is a 'once and for all' decision, that communication does not change over time, or that differing communication modes may be used in differing situations. However, children with cochlear implants do change communication mode after implantation, particularly if implanted early (Watson et al., 2006). Most parents have changed communication mode following implantation. The trend is markedly towards an increase in oral communication, even for children who had initially used signed communication. Parents' views are that this shift was largely driven by the change in access to audition provided by the implant and was led by the child's changing needs and own choice. Those implanted younger were more likely to change communication mode from sign to oral and did so more quickly than those implanted later, with 83 per cent of those implanted below the age of three using oral communication exclusively 5 years after implantation. As per researchers, majority of cochlear implanted children have moved from signed communication to oral within 6 months of implantation. Parents and young people have showed interest in the use of some signed support or Sign Language (e.g. BSL/LSL/ASL), once spoken language had been established. Thus, while cochlear implantation offers increased opportunity for the development of oral communication, parents have recognized that differing approaches may be appropriate at differing times, and this might include the use of signed communication. The concept that parents have to make a 'once and for all' decision about communication mode, shortly after diagnosis has been changed by cochlear implantation. Challenges: For educators, cochlear implantation has provided new opportunities, but also new challenges to address: Providing flexibility in educational provision over time. Providing effective support in mainstream, inclusive educational settings. Supporting a more diverse population with more subtle communication needs. Monitoring subtle changes in progress over time, and identifying difficulties which may impede progress, whether these originate in the child, the environment, or in the technology.

131 Providing appropriate education for those who have an additional learning disability. Providing appropriate support for the increasing demands in the secondary, school setting. Managing complex, changing technology in a busy educational environment. Collaborating effectively with a greater number of professionals. Providing peer-group support for the psycho-social needs of the increasing numbers of those in mainstream settings (Archbold, 2010). There remains the challenge of long-term management in education for this new group of children, who are deaf but functioning with levels of hearing provided by implantation not previously possible for profoundly or severely deaf children, and who are increasingly using two implants. They are not functioning as profoundly deaf children of the past, but neither do they function as hearing children. Communication options for early identified children having access to good amplification: Children who have been screened early and fitted with hearing aids before the age of six months reach a higher expressive and receptive language level, their speech is more intelligible, they have higher auditory capacities, fewer social-emotional problems, their parents have better attachment, they become better readers and more and more of these children are going to a mainstreamed educational setting. The Simcomm (Simultaneous communication) approach has evolved to be a better approach for early identified children fitted with good quality hearing aids or cochlear implants. Challenges: Transition from sign to spoken communication is dependent upon the age of hearing aid fitting. Children fitted before eighteen months of age are able to make the transition well. However, if hearing aid fitting occurs after thirty months of age, the probability of transition from sign to speech is significantly reduced. Several factors have been identified which affect the communication option opted by the family and the child fitted with hearing aids. These factors include: Continuing debate concerning the appropriate language(s) of instruction in deaf education (e.g. speech alone, cued speech, speech+sign). Still-evolving approaches for developing speech and auditory capacities in hearing aid users.

132 Individuals' receiving their hearing aids relatively late (3-12 yrs of age) Pre-fitting language and cognitive abilities Concomitant neurological or psychological conditions Post-fitting educational methodologies Greater complexity and abstractness of reading materials for older students Degraded signals provided by hearing aids which restrict full access to spoken language. Communication options for late identified children having access to good amplification: The single most important factor in determining successful development of spoken language after successful identification of hearing loss is the age of hearing aid fitting and commencement of speech, language therapy and remedial education. The younger a child is intervened, the more likely they are to be able to understand spoken language and to use intelligible spoken language for everyday communication. Universally for late intervened children, Sign is used in conjunction with speech (total or simultaneous communication) or a sign language such as British Sign Language (BSL), Indian Sign Language (ISL) or American Sign Language (ASL) is used as the child's first or primary language, with spoken or written English being introduced as a second language. The following pattern proposed by Archbold et al. (2000) has been advocated. This includes: Oral communication approach: the child was communicating at home and school and being educated by means of spoken language. Sign communication approach: the child was communicating and being educated using sign for all or part of the day and to whatever degree; this included use of spoken English with sign support (total or simultaneous communication) and the use of sign language (Archbold et al. 2000). Challenges: The sensitivity of the central nervous system and neural plasticity is an important concern. While the effects that deafness may have on neuronal connectivity within the auditory pathway have yet to be defined, neural plasticity of the brain in infants has been discussed when considering early intervention. It seems that those intervened over the age of 3 may need more time to adjust

133 to the new signal being received through hearing aids, and are less likely to change from a signed approach to an oral approach, and some who do change are likely to take longer in comparison with those intervened at an earlier age. Adaptability to change is another issue. Those children who do not change from sign to oralism or take longer time to change are because their communication pattern would have been more firmly established. Globally, despite growing consensus for early identification of hearing loss congenitally deaf children generally spend at least 3 years with only very limited access to sound and even if any still learn to use vision as their primary or sole route to communication. In order to change from the use of a visual system, which utilizes a sense that for the majority is unimpaired, the auditory signal will need to become the more salient route for communication and this process takes years not months to be developed. 4.7

Tuning the environment (Home & school) for facilitating Language and Communication

The child's communication approach would be considered as one factor in the decision regarding school placement. For children who were intervened between the ages of 3 and 5 and those who used sign when they started school, their placement will differ significantly. Once a child starts school, there is a pressure on educationalists to ensure that the child accesses the curriculum. The emphasis is on teaching and ensuring that the child has grasped significant concepts and accessed information. If the child's language development is delayed compared to their hearing peers, then the pressure to ensure that the child can access the curriculum will be increased. Staff may have less time available to spend in promoting the child's listening skills, either in a global way by encouraging the child to listen and presenting auditory cues first, followed by visual cues as necessary, or by engaging the child in discrete listening activities. It is also possible that the expectations of staff, maybe born out of experience of signing deaf children with hearing aids, are that children who start to use sign do not change, whereas in reality children intervened early and fitted with good quality hearing aids have better spoken language, and over time this may change the child's communication use. Classroom adaptations for children with hearing impairment: IN LOWER GRADES:

134 Preferential sitting Use of FM system/traditional amplification along with hearing aid. Selection of classroom with good acoustics and low noise level Regular monitoring of hearing and gain levels. Regular assessment of speech perception IN HIGHER GRADES: Curriculum based assessment Use of assistive devices Identifying strengths and weaknesses Capitulating on the individual's strength Enhancing written more than oral usage of language Using sign language/ SimCom if the individual is adapted with its use. Identifying courses which the individual will have ease of study. 4.8 Let Us Sum Up Structured method believes that language is teachable hence has to be taught. It advocates the use of symbol system to represent the structure. The students are made to work on grammar rules by analyzing, categorizing the grammatical aspects. It advocates the use of memorization and imitation work in developing patterns of language. The natural method believes that language is not teachable but rather learned. One has to ensure exposure and input and the children "learn" the language naturally.

The child is expected to acquire language implicitly through interaction occurring within the environment. No symbol system is used. The main emphasis is on the development of language via oral conversation method based on the experience of the children as it happens naturally in the home environment and the instructions are all planned to parallel the sequence of language acquisition in hearing children. The combined method utilizes components of both structured and natural method.

135 SimmComm, Total Communication and Bilingualism are some of the combined methods. The Oral method and Sign Language are the two most widely used and highly debated methods of communication for the deaf. Some believe the Oral communication method to be most beneficial for deaf individuals while some agree on Sign Language to be the most beneficial method. Children with cochlear implants change their communication mode after implantation, particularly if implanted early. Most parents have changed communication mode following implantation. The trend is markedly towards an increase in oral communication, even for children who had initially used signed communication. Children who have been screened early and fitted with hearing aids before the age of six months reach a higher expressive and receptive language level, their speech is more intelligible, they have higher auditory capacities, fewer social- emotional problems, their parents have better attachment, they become better readers and more and more of these children are going to a mainstreamed educational setting. 4.9 Check Your Progress 2. What are the factors that affect integration of a child with hearing impairment in normal school? 3. What is structured method of language teaching for children with hearing impairment? 4. What are the educational problems faced by children with hearing impairment in the Indian context at various levels. 4. What are the differences between American sign language and Indian sign language 5. What is natural approach? Why is natural approach superior over structured method 6. What are the classroom adaptations for children with hearing impairment?

Educational Intervention If your child is receiving help in school you will have no hesitation to hear the term intervention. A set of people apply this declaration loosely, to express any kind of assistance once a child gets. But intervention has a very particular definition. Knowing what the term means puts you in an improved position to understand the help your child is getting in school. That is why Educational Intervention is a most important part of an education system. An Educational intervention is a specific program or set of steps to help a child improve in an area of educational need. Like reading or math, there are instructional interventions and also sometimes called academic interventions. In this regard education intervention has various education programmes like pre- school, primary, secondary and high secondary in inclusive setup. The education also underwent changes in the philosophy, mode of communication, teaching methods, curriculum, evaluation etc. In the light of this there are two types of key elements of Educational Intervention concept. These are: Educational intervention— I. Aimed at a particular weakness. II. Specific and formal. Aimed at a particular weakness : That means the educational programmes have become need based of the child and search the particular weakness where the children are not capable of the subject orientation programme. Example: In academic progress hearing impaired children particularly in deaf, he/she can use in picture where the comprehend language is used which relies heavily upon the language skill. Specific and formal. That means the educational programmes in hearing impairment have become mainly fostering the academic achievement in specific formal way towards the mainstream atmosphere.

5.3.1. Needs and Areas of Educational Intervention in H.I. To understand

the difficulty that students with hearing impairments may have in presenting oral reports are the potential language development problems linked to hearing impairments and they cannot articulate words clearly. So these educational obstacles related to hearing impairments stem around communication. A student with a hearing impairment may experience difficulty in: the subjects of grammar, spelling and vocabulary taking notes while listening to lectures participating in classroom discussions watching educational videos presenting oral reports

So from the above Points, Educational Intervention take a major role in a hearing impaired child. That is why Educational Intervention can play a great role to monitor a child's hearing, speech, and language development. The different varieties of needs used for documenting children's development are beyond the scope of this module. The needs are:

5.3.2. A-Speech and Language development

The ability to learn language and speech is the most severely affected area of development of the hearing impaired child. That is, without extensive training the hearing impaired child will not develop normal language and it is a great barrier to normal language development. So Speech and Language development is the most important part of a hearing impaired child.

B-Intellectual Ability Development

Thinking process of normal and deaf children are found to be similar. Cognitive abilities of deaf children are same as normal without language and it is called non-141 verbal intelligence. Hence, a hearing impaired children get a higher score in non- verbal intelligence.

C-Academic Achievement Performance

Hearing impaired children are frequently handicapped in varying degree of educational achievement and they are particularly handicapped in reading which relies heavily upon language

skills. Only small percentage of deaf or hearing impairment individual comprehend language well enough to read text book. So in this regard, academic achievement of deaf children is mainly due to the fact that academic atmosphere in school and colleges is predominantly verbal in nature and that the deaf children have deficiency in verbal skills. D-Social and Occupational Adjustment Social and personality characteristics of hearing impaired children are markedly different from the normal children because social interaction depends upon communication with the speech. A hearing impaired child particularly deaf focus trouble in communicating with speech. This agreement the problem of social adjustment. Due to this such children live in a world of isolation. Due to such isolation hearing impaired children develops a sense of inferiority and frustration in the hearing impaired children. Areas of Educational Intervention There are mainly two important aspect of Educational Intervention. These are Curricular and co-curricular part. A-Curricular You all are skilled teachers of the students with hearing impairment and not required to explain what curriculum is; nor do you need to be told what adaptations are? However, it is always better to start from the beginning ensuring that one is absolutely clear about the basic concepts involved. Hence let us just quickly brush up what we know about 'curriculum' and 'adaptations'. Curriculum, in general is a detailed blueprint of 'what to teach' and 'how to teach' which includes the following aspects :

- (1) Objectives of Teaching Learning Process (TLP)
- (2) Content (subject matter) of the TLP
- (3) Speed and duration of TLP
- (4) Classroom curricular transaction strategies.
- (5) Calendar and schedule of activities and experiences required for facilitating TLP.
- (6) Teaching Learning Material (TLM) required for TLP.
- (7) Assessment strategies- formative as well as summative.

The curriculum must: Include child centred pedagogy keeping in mind the child's psychological development, interests and specific learning needs Ensure equal access in every possible manner like physical, attitudinal, academic and social. Facilitate learning in an inclusive learning environment with accessible material, positive attitude and relevant/adaptive teaching strategies. Prescribe for use of all available educational / assistive technologies to ensure equal participation of and effective learning in all children specifically for children with hearing impairments. Include all children with and without hearing impairment needs by providing differential opportunities to demonstrate learnt skills according to their learning abilities. Adaptation: Adaptation is an ongoing dynamic process that modify and adapts the IEP/ prescribe programme to meet the learning requirements of a student with hearing impairment and ensure that every student is challenged to learn. Adaptation must : Include components of life skills through transitional stages working towards independent living. Include locally available conditions/ opportunities/ situations to develop pre- vocational and vocational competencies. Integrate work pedagogy in education and include broad-based work experiences taking care of the needs of hearing impaired children. 143 Ensure participation of hearing impaired children in play, games, social and cultural activities to improve the physical and mental health by developing appropriate adaptations. Provide flexibility in school and class time tables to address individual needs of children Create opportunities for facilitated social interaction. Construct knowledge by connecting new ideas to existing ideas on the basis of materials/ activities. Incorporate required adaptation in curriculum (learning content, learning approach, learning aids and evaluation) to address and accommodate individualised learning styles.

B-Co-curricular A Child's holistic development is measured not only by his academic achievements. Sports & Games, Arts & Fine Arts and social skills combined together with intellectual excellence makes a student what he or she will be when he blossoms into an adult. In view of this opens an avenue of Co-curricular activities to prepare children with hearing impairment for his greater journey of life's-curricularactivities are not just 'nice to have' or 'desirable to have', but 'must have' qualities and this activity are like Yoga, Music, Dance, Sports and other activities moulds the wholesome personality in students and implementedfor character development in students. Types of Educational Intervention Education completes man. Students need quality education suitable for life. Perceiving the needs of the learners, appropriate changes are made in the curriculum, syllabus and textbook on a need basis. Currently changes have taken place in the evaluation system. The long-practiced marking scheme has been done away with and grading system has been brought in its place. The students are assessed not only during examinations but all through the term. Education intervention is conducted through activities in two broad senses. These are curricular and co-curricular activities. In this regard, there is no single type of Educational Intervention. So the prevalent types of Educational Interventions are group, individual, developmental and remedial.

A-Group: There is a range of inclusive teaching strategies that can assist all students to learn but there are some specific strategies that are useful in teaching a group which includes students with hearing impairments. The solution to all the problem arising out of formation of various levels within a group hence is known as grouping for instruction. The highlights of the grouping system are: There is no rigid class. All children of a same class do not remain within the same group or all subject. Children are grouped according to their abilities, strengths or weakness and are taught accordingly by separate teachers in separate class room. Type of flexibility within the group for instruction exists for most of the curricular and co- curricular lessons in the schools where grouping are practiced. It is an ideal way which could give an opportunity to each and every child to learn appropriately at his/her pace and as per the ability.

B- Individual: Man is a social animal and cannot live without society. Individuals are part of the society and the society in turns has many expectations from every individual. So both should contribute each other and individuals must acquire social efficiency. But society believes that education is necessary only for able children. Due to this hearing impaired children are often unnoticed resulting in ignorance of the society towards educational needs and social participation of the children with hearing impairment. A special education program should be customized to address each individual student's unique needs. A special educator provides a continuum of services, in which students with hearing impairment receives varying degrees of support based on their individual needs. Special education programs need to be individualized so that they address the unique combination of needs in a given student. In special education educational professionals use a student's Individualized Education Programmed "The IEP is meant to address each child's unique learning issues and include specific educational goals. It is a legally binding document. The school must provide everything it promises in the IEP. So with the help of IEP students with hearing impairment are assessed to determine their specific strengths and weaknesses and teacher produce the children's

145 placement, resources and goals. These are determined on the basis of the student's needs. Accommodations and Modifications to the regular program may include changes in the curriculum, supplementary aids or equipment, and the provision of specialized physical adaptations that allow students to participate in the educational environment as much as possible. Parent of students with hearing impairment must know what type of disability their child has, so they can get accommodations like speech therapy, auditory training etc. For example, if a student takes an academic test and it indicates that the student struggles with reading comprehension; parents can request speech and language support or classroom accommodations, such as extra time to complete reading and writing tasks.

C-Developmental: Developmental Education intervention must involve ongoing teamwork and discussion with parents and other service providers (therapists or special education teachers, assistants and one-to-one aids) involved in delivering in developmental education intervention services to each eligible child participating in the group and the child's family. Families must collect steady response on the child's progress, based on the needs of the child and family. In addition, families should receive feedback on how they can help their child learn and work on skills to support learning and development in the home environment. Developmental education intervention services should include the supports and resources (e.g., assistive technology, curriculum adaptations and equipment) necessary to maximize the child's opportunities to participate and learn in the group setting and services should use developmentally appropriate practices that are also responsive to cultural and language needs of the children in the group.

Guidelines for Selecting Developmental Education Intervention

What are the child's unique strengths, developmental needs and skills, interests, health status and history that contribute to the consideration of a group setting? If services are recommended for a child with health issues, what precautions and supports are necessary to ensure the child's health status will not be compromised in a group setting? Considering the child's chronological age and developmental status, in what ways might he or she benefit from participating in group services? What are the planned approaches and activities in a group setting necessary to

support the transition of the child to a typical preschool or preschool special education program? What types of adaptations, modifications, supports, and equipment might be needed to enhance the child's participation in the group setting? What characteristics of the group setting are important to achieve the goals and measurable outcomes in the child's and family's and to help the child benefit from the group experience. e.g., type of intervention model, need for staff fluent in the child's language, cultural considerations etc. D-Remedial: Remedial Education Intervention is also known as developmental education, basic skills education, compensatory education, preparatory education, and academic upgrading. It is signed to assist students in order to achieve expected competencies in core academic skills such as literacy and numeracy. Whereas special education in children with hearing impairment is designed specifically for students with hearing impairment. remedial education intervention can be designed for any students, with or without special needs; the defining trait is simply that they have reached a point of under preparedness, regardless of why. 5.4 Principles and Practices in Early Educational Interventions Family Centered, Contextualised (natural and inclusive environment) and Integrated (Collaborative) Support and Services 5.4.1 Introduction: Now our formal education is started from very early childhood. A child can go to school from 2 years + . There are many play schools for children. According to rule of our Govt. formal education is started from 5 years + in primary school. The children who belong to the age group of 5 years + to 6 years get education in pre-primary classes. There after they start their primary education from Class I. The children get support in the corner of nutrition, health and non-formal education also. The children of 0-5 years can go to the Anganwadi Centres. But the informal education is started from birth by the pleasant touch of mother. A child grows gradually in nature and he/she becomes a member of his/her family. So, then he/she starts to learn anymore from his/her family and surrounding also. We can say that a family has the important 147 role to develop the child. Every child is quite individually different from each other. So every child has different capability also. We should prepare various types of curriculum according to ability to fulfil their needs. 5.4.2 Principles: Early childhood education is the most important part in the life. Before 5 years a child can get education through informal and non-formal ways. But many play schools introduce formal education by playway techniques. So they follow some basic principles. These are : The educational goal must be child centrie. A child is a main component of education. So the main objective of education is to fulfil the needs of a child. The age limit of the education must be below 5 years. The education of below 5 years is called early childhood education. The education must be activity based. A Child likes to do activities. They can learn easily through more and more activities. The curriculum must be friendly. A child always wants to meet with his/her friends. They like to play with themselves. So, if the curriculum is filled up with joy a child can accept it spontaneously. The curriculum must be flexible. The curriculum can be charged on the basis of needs, time and environment also. The curriculum must be developed from simple to complex. The teaching or learning should be started from simple to complex. As a result the child acquires the concept easily. The curriculum must have the indication from known to unknown. If the learning activities are started from familiar situation to unfamiliar situation or known experience to unknown experience the child can learn anything properly. The curriculum must be prepared on the basis of interests and tendencies of the children. The Curriculum must be made from concrete to abstract.

In early childhood a child wants to observe all by touch, So, the curriculum should be prepared such a way that are fulfilled with many activities of concrete materials. 5.4.3 Family Oriented Programmed in Early Childhood Education : A child grows gradually in his/her own family. Every child becomes mature by the warm and nice touch of his/her family members. During the period of 0-5 years nature and family atmosphere both play the vital role. The family members continuously assist the child to adapt with nature and surroundings. The growth and developments of the children both are running on at the high rate before 5 years. So, the parents and other family members should keep it up in the mind that a child wants more support at that age particularly. Many research have already shown that if any child becomes strong physically and mentally at that age he/she can spend a healthy life for ever. The parents should spend the quality time with their child. In early childhood the every child wants to imitate someone who is the ideal to that particular child. The child often likes somebody and so he/she follows each activity of that person. Actually that person is the role model to the child. So, the family members or adult should be very much careful to nurture their little one. The child tries to accept all the behaviour of their guardians by imitation. We can say that early childhood is the crucial age of every life. Now our children with special needs start their journey as same as normal children. But the children with special needs demand extra support. Often many techniques and different methods are used to facilitate them. Suppose we have a learner who is a child with hearing impairment. Now there is a question how will we give fruitful instructions which are more beneficial for him to communicate with others. 5.4.3.1. Steps to follow : First of all we should remember that a HI child wants to show some gestures to interact with other. He points out some objects by the use of fingers. But we know very well that it is not enough. So, we can follow some procedural steps. Early detection is the most effective task to us. If this type of disability is detected after birth (0-6 months) by the parents the next attempt may be easy. After detection the parents should go for disability certification to measure the level of disability. According to level the parents should give him hearing aid. It is their duty to

149 make him habituated for the use of hearing aid. At the beginning the child does not want to use hearing aid. He often puts off hearing aid. The parents should be careful about it that he does not put off his aid. After habituation of use of hearing aid the family members should arrange different types of instruments (rattle, bell etc) or objects with various tones and tunes. The members will create the sound in front of him and utter clearly the names of those instruments or objects. This practice will continue on regular basis. The number of the instruments or objects are increased day by day. After identification of a sound we can proceed for another sound. Then he will be able to discriminate each sound among others. There after he can comprehend many sounds. It is an ordinary task of auditory training at home. Simultaneously we can show him many objects in front of him and properly pronounce the word repeatedly. It must be the face to face interaction. The parents must encourage their child to utter those words. At that time the child can try only not perfectly. After that the child needs more picture clues. The picture must be clear and colourful. It is quite natural that at that age the little one will become curious and investigative. Then he enquires very much. The family members should give him reply clearly to fulfil his requirement. The child needs love and care. The family members should not avoid or joke with him. They should keep up patience while they talk with their child. If the child feels that he is a victim he will stop the communication. The parents should send him for play with peer groups. The communication should be increased gradually. Here the parents can follow a technique which is called lip reading. When an adult talks with the child he/she should care it that the child can observe his/her lips clearly or not. The sentences must be simple and short. Dramatization is another effective technique. The family members can play the short roles to establish different characters or to make him realize many abstract thoughts. The child will also involve in it. But the adults will not express to the child that it is not true. They should present whole as same as real life. Thus the child can develop his speech and interaction with others. The parents should create the environment as if the child wants to interact with another member of the family spontaneously.

5.4.4 Inclusive Support According to RTE Act (2009) every child has a right to get formal education under the same roof. Sarva Siksha Mission (SSM) has already said that no child will be isolated due to his/her disability. On the other hand SSM has a slogan—'no discrimination'. So, every year SSM provides many grants to prepare TLM for the children with special needs. Now every school (directly Govt. & Govt. undertaken) has been transformed into inclusive school. In our West Bengal Govt. aided many schools are under the same circle. Every circle has a resource room where the special education are appointed through needs go to the resource room twice in a week. They get proper assistance on the basis of their requirement. The special educators are expert in different field of disability. Every special educator is responsible for many special need children of different schools within the circle. They visit regularly in every school and submit their report to the circle office (Circle Level Resource Centre—CLRC) as well as SSM. First of all they take report from the Head of the Institution of every school at the beginning of the session if any child with special need is admitted or any type of disability has been detected by the responsible teachers. There after he/she gives suggestions to the responsible teachers how the child will overcome the difficulties. If the teacher wants he/she can prepare different types of TLM for the child with special needs with the help of special educators. The teacher can enquire how he/she will use that activity of the learners. The special educator helps the responsible teacher to make up the teaching of children with special needs. Often SSM provides orientation programme for the teachers. The teacher should follow the techniques and methods which are demonstrated in orientation programme. Every child wants empathy not sympathy from us. So, it is high time to take necessary steps for the children. 5.4.5 Integrated Supports & Services If the child has high degree of hearing loss he needs support of some special techniques which are executed in special schools where special teacher facilitation the child how to apply some techniques in home. So, we can say that home and special school are not fully different unit but both are dependent to each other. The child can learn

151 the techniques and methods properly by the assistance of special teachers and then he may practice those techniques in home with his family members. The family members can also learn the techniques from the teachers. As a result they can rectify the child when he practices. According to RTE Act (2009) the child starts to go to normal school from 5 years + . There he meets with many friends and teachers. If the teachers of normal school have been known with such methods of communication with HI children they can develop his communication skill. The special school is not an isolated body but it can work with other associated bodies such as normal school, parents, family members and peers group etc. Thus the HI child can progress his speech. Below 5 years a child goes to Anganwadi centre. He gets chance to make friendship among the children there. The centre-in-charge should follow the techniques to interact with her learner. If she thinks that she needs adequate support of guardians she may call them and may take the help. A word must be kept in mind that integration is possible when all of us want to provide effective assistance to the child. 5.5.

Maxim, Methods of teaching & Lesson planning (group, individual and developmental, remedial) 5.3.1. Maxim, Methods of Teaching Every teacher or special educator wants to make maximum involvement and participation of the learners in the learning process. He sets the classroom in such a way so that it becomes attractive for them. He uses different methods, rules, principles etc. in order to make his lesson effective and purposeful. He uses general rule or formula and applies it to particular example in order to make teaching -learning process easy and up to the understandable level of students. These settled principles, tenets, working rules or general truths through which teaching becomes interesting, easy and effective are called the maxims of teaching. They have universal significance. Every person who is expected to enter into the teaching profession has to familiarize himself with the maxims of teaching. Their knowledge helps him to proceed systematically. In this context of Hearing Impaired Learners it is very much important to say that expression through language is the main barrier of learning. So all the times it is keep in mind that all words are new to them.

The different maxims of teaching are briefly explained below. The teacher or special educator should always proceed keeping them in view.

1. From known to unknown: - When a child enters into school, he possesses some knowledge and it is the duty of teacher to expand his previous knowledge. In case of Hearing Impairment (HI) students the teacher to expand his / her language also. Whatever he possesses should be linked with the new knowledge and language. If we link new knowledge with the old knowledge our teaching becomes clearer and more definite. This maxim facilitates the learning process and economises the efforts of the teacher and the taught. For example, is teaching English to the children and he is to teach the word 'water'. This way of teaching helps the learners to understand things fully. This way the teaching becomes definite, clearer and more fruitful. Example: - Water (Know) Stream (Unknown).
2. From simple to complex: - The main objective of teaching is to teacher and the learner's objective is to learn something. In this process of teaching and learning, simple or easy things should be first presented to the students and gradually he should proceed towards complex or difficult things. The presentation of simple material makes the learners interested, confident and feel encouraged. As they will show interest towards the simple material, they become receptive to the complex matter. On the other hand, if complex matter is presented first, the learner becomes upset, feel bored and finds himself in a challenging situation. For example, in mathematics we first present the idea of addition (+), subtraction (-), multiplication(\times) and then division. When the hearing impaired students gets admitted to 9th and 10th class we introduce algebra, square, trigonometry, geometry etc. As he proceeds further he becomes familiar with the complex material like matrices, integration, differentiation etc. In this way a learner shows interest by proceeding from simple mathematics to complex one. But if we reverse the situation, he will find himself in a challenging situation and will left his studies due to complexity of matter. Simplicity or complexity of the subject matter should be determined according to the view point of the learners. It makes learning convenient and interesting for the students.
3. From concrete to abstract: - Concrete things are solid things and they can be visualized but abstract things are only imaginative things. The child understands more easily when taught through their senses and never forget that material. On the other hand, if abstract things or ideas are presented, they forget it soon. As Froebel said, "Our lessons ought to start in the concrete and end in the abstract". For example, when we teach the solar system, we first visualize the sun through our senses and gives the concept of eight planets, galaxies, meteorites etc. Through this process, the learners understand the materials more easily. Some power of imagination also develops in them. But if we reverse the situation, it will become difficult for learners to understand anything. Another example, when we teach counting to the students we should first take the help of concrete objects like beads, stones etc. and then proceed to digits and numbers.
4. From analysis to synthesis: - When we divide a thing into easy parts or separate elements in order to understand it easily is called analysis. It is the process which helps in understanding the hidden elements of a thing or the cause of some incident or behaviour. For instance, in order to tell about the structure or functions of heart, the parts of the heart are shown separately and knowledge of every part is given. After it the students are made to understand the structure or system of working of the heart. In this way, even a very difficult thing can be easily understood. Synthesis is just opposite of analysis. All parts are shown as a whole. The process of analysis is easier than synthesis for understanding a thing. This process develops the analytical power of the students. It is the best method of starting the teaching process. For example, while teaching digestive system, we should first analyse the different parts of digestive system one by one and then gives the synthetic view of it. Hence a good teacher always proceeds from analysis to synthesis.
5. From particular to general: - A teacher should always proceed from particular to general statements. General facts, principles and ideas are difficult to understand and hence the teacher should always first present particular things and then lead to general things. Suppose the teacher is

teaching continuous tense while teaching English, he should first of all give few examples and then on the basis of those make them generalize that this tense is used to denote an action that is going on at the time of speaking. Hence a teacher should proceed from particular to general. 6. From empirical to rational: - Empirical knowledge is that which is based on observation and first and experience about which no reasoning is needed at all. It is concrete, particular and simple. We can feel and experience it. On the other hand, rational knowledge is based upon arguments and explanations. For example, suppose the students are to be taught that water boils on heating. They should first be made to heat the water and see it boiling. Then the teacher should explain that when water is heated, the molecules gain kinetic energy and there is thermal agitation of the molecules which make the water boil. This maxim is an extension of some of the previous maxims, namely proceed from simple to complex proceed from concrete to abstract and from particular to general. 7. From induction to deduction: - The process of deriving general laws, rules or formulae from particular examples is called induction. In it if a statement is true in a special situation, it will also be true in other similar situations. It means drawing a conclusion from set of examples. For example, when hydrogen reacts with boron, it gives Boron hydride, potassium reacts hydrogen, it gives potassium hydride, we come to the conclusion that all elements when reacts with hydrogen they form hydrides. While using this process in teaching, a teacher has to present particular examples or experiences and tell about similarity of their attributes. Deduction is just opposite of induction. In it, we derive a certain particular conclusion from general laws, rules or principles. For example, in language teaching, before giving the definition of noun, the students are acquainted with the example of noun like man, chair, Delhi etc. and then they are led to general definition of noun. So a good teacher always proceeds from induction and finishes at deduction. 8. From psychological to logical: - Modern education gives more emphasis on psychology of the child. The child's psychological development is of utmost important than any other thing. A teacher while teaching should follow this maxim viz from psychological to logical. Psychological

155 approach takes into consideration the pupil his interests, abilities, aptitudes, development level, needs and reactions. The teacher should keep in mind the psychological selection of the subject matter to be presented before the pupils. Logical approach considers the arrangement of the chosen content into logical order and steps. It is child centered maximum. For example, a teacher tells the story of a poem to students when they are not interested in reading, with this a teacher proceeds from psychological to logical sequence. 9. From Actual to Representative: First hand experiences make learning more vivid and efficient than to give them representative ones. A teacher while selecting the content for presentation should make all efforts possible to present it through actual, natural or real objects than from their improvised representative one's like pictures, models etc. For example, to teach about 'Golden Temple Amritsar', a teacher should try his best to visit the actual place and that learning will be more vivid and the pupils will retain it for a long time in spite of teaching through sketches, model or a picture. Representative forms should be used at the higher classes than in lower classes. 10. From Whole to Parts: This maxim is the offshoot of gestalt theory of learning whose main emphasis was to perceive things or objects as whole and not in the form of parts. Whole is more understandable, motivating and effective than the parts. In teaching, the teacher should first give a synoptic view of lesson and then analyse it into different parts. For example, the teacher while teaching the pollination in plants, he should first take the flower then analyse it into different parts and give detailed information about each and every part like the sepals, petals, androecium, gynoecium etc. In this way, maximum learning is possible. It is actually the reverse of the maxim "analysis to synthesis". 11. From definite to indefinite: A teacher should always start from definite because definiteness has its limited boundaries and jurisdiction than indefinite things. We always have confidence on definite and tested things. We learn easily indefinite things on the basis of definite things. Hence a teacher while teaching any content should first present definite things, ideas and then he can learn indefinite things easily. Definite things, definite rules of grammar help the

learner to have good knowledge. Gradually he can be taught about indefinite things. The above method also applicable for hearing impaired students, not only the specific students any students can learn from the above method. This is a very important for the student to be trained for five senses (eye, ear, nose, test, & touch) in the teaching field. It all these organs are always active, students learnt every things very quickly. With the help of sense organs students are able to from concept in their mind about size in this universe, types, colours, weight, quantity ,density and temperature etc. If the sense organ work properly the concept of each object also develop correctly in students. LESSON PLANNING A lesson plan is a teacher's detailed description of the course of instruction, or 'learning trajectory' for a lesson. A daily lesson plan is developed by a teacher to guide class learning. Details will vary depending on the preference of the teacher, subject being covered, and the needs of the students There may be requirements mandated bypassed the school system regarding the plan. A lesson plan is the teacher's guide for running a particular lesson, and it includes the goal (what the students are supposed to learn), how the goal will be reached (the method, procedure) and a way of measuring how well the goal was reached (test, worksheet, homework etc.). Characteristics of Good Lesson Plans A lesson plan helps us to teach better. A big part of having lesson plans is being able to track your teaching activities throughout the term. For example, start with the objective, or what you want students to learn from the lesson, and link it to the overall course objectives and state standards. This not only keeps you accountable but also helps you keep track of how you are meeting course objectives. Your lesson objectives should be viewed as, 'what will the students learn today?' or 'what can they do with this information, afterwards?' The Flowchart below may serve as a reference for teachers in the delivery of collective or group or individual teaching.

157

Steps for Preparing a Lesson Plan A lesson plan is the instructor's road map of what students need to learn and how it will be done effectively during the time. Before you plan your lesson, you will first need to identify the learning objectives for the class meeting. Then, design appropriate learning activities and develop strategies to obtain feedback on student learning. A successful lesson plan addresses and integrates these three key components: Objectives for student learning Teaching/learning activities Strategies to check student understanding Specifying concrete objectives for student learning will help you determine the kinds of teaching and learning activities will use in class, while those activities will define how you will check whether the learning objectives have been accomplished. (1) Outline learning objectives The first step is to determine what you want students to learn and be able to do at the end of class. To help you specify objectives for student learning, answer the following questions: What is the topic of the lesson? What do I want students to learn? What do I want them to understand and be able to do at the end of class? What do I want them to take away from this particular lesson? Once you outline the learning objectives for the class meeting, rank them in terms of their importance. This step will you for managing class time and accomplishing the more important learning objectives in case you are pressed for time. Consider the following questions: What are the most important concepts, ideas, or skills I want students to be able to grasp and apply? Why are they important? If ran out of time, which ones could not be omitted? And conversely, which ones could I skip if pressed for time?

159 (2) Develop the introduction Now that you have your learning objectives in order of their importance, design the specific activities you will use to Search students to understand and apply what they have learned. Because you will have a diverse body of students with different academic and personal experiences, they may already be familiar with the topic. That is why you might start with a question or activity to gauge students' knowledge of the subject or possibly, their preconceived notions about it. For example, take a simple poll: "How many of you have heard of X? Raise your hand if you have." You can also gather background information from your students prior to class by sending students an electronic surveyor asking them to write comments index cards. This additional information can help shape your introduction, learning activities, etc. When you have the students' familiarity with the topic, you will also have a sense of what to focus on. Develop a creative introduction to the topic to stimulate interest and encourage thinking. You can use a variety of approaches to engage students (e.g., personal anecdote, historical event, thought-provoking dilemma, real-world example, short video clip, practical application, probing question, etc.). Consider the following questions when planning your introduction: How will I check whether students know anything about the topic or have any preconceived notions about it? What are some commonly held ideas (or possibly misconceptions) about this topic that students might be familiar might espouse? What will I do to introduce the topic? (3) Plan the specific learning activities (the main body of lesson) Prepare several different ways of explaining the material (real-life examples, analogies, visuals, etc.) to catch the attention more students and appeal to different learning styles. As you plan your examples and activities, estimate how much you will spend on each. Build in time for extended explanation or discussion, but also be prepared to move on quickly different applications or problems, and to identify strategies that check for understanding. These questions would help design the learning activities you will use: What will I do to explain the topic? What will I do to illustrate the topic in a different way? How can I engage students in the topic? What are some relevant real-life examples, analogies, or situations that can help students understand the topic?

What will students need to do to help them understand the topic better? (4) Plan to check for understanding Now that you have explained the topic and illustrated it with different examples, you need to check for student understanding - how will you know that students are learning? Think about specific questions you can ask students in order to check understanding, write them down, and then paraphrase them so that you are prepared to ask the questions in different Try to predict the answers your questions will generate. Decide on whether you want students to respond orally or in You can look at to help you generate ideas and you can also ask yourself these questions: What questions will I ask students to check for understanding? What will I have students do to demonstrate that they are following? Going back to my list of learning objectives, what activity can I have students do to check whether each of those been accomplished? An important strategy that will also help you with time management is to anticipate students' questions. When planning lesson, decide what kinds of questions will be productive for discussion and what questions might sidetrack the class. about and decide on the balance between covering content (accomplishing your learning objectives) and ensuring that students understand. (5) Develop a conclusion and a preview Go over the material covered in class by summarizing the main points of the lesson. You can do this in a number of you can state the main points yourself ("Today we talked about..."), you can ask a student to help you summarize them, you can even ask all students to write down on a piece of paper what they think were the main points of the lesson. review the students' answers to gauge their understanding of the topic and then explain anything unclear the following Conclude the lesson not only by summarizing the main points, but also by previewing the next lesson. How does the relate to the one that's coming? This preview will spur students' interest and help them connect the different ideas within larger context. (6) Create a realistic timeline GSIs know how easy it is to run out of time and not cover all of the many points they had planned to cover. A list often learning objectives is not realistic, so narrow down your list to the two or three key concepts, ideas, or skills you want students to learn. Instructors also agree that they often need to adjust their lesson plan during class

161 depending on what students need. Your list of prioritized learning objectives will help you make decisions on the spot and adjust your lesson plan as needed. Having additional examples or alternative activities will also allow you to be flexible. A realistic timeline reflects your flexibility and readiness to adapt to the specific classroom environment. Here are some strategies for creating realistic timeline: Estimate how much time each of the activities will take, then plan some extra time for each When you prepare your lesson plan, next to each activity indicate how much time you expect it will take Plan a few minutes at the end of class to answer any remaining questions and to sum up key points Plan an extra activity or discussion question in case you have time left Be flexible - be ready to adjust your lesson plan to students' needs and focus on what seems to be more productive rather than sticking to your original plan Presenting the Lesson Plan Letting your students know what they will be learning and doing in class will help keep them more engaged and on track. You can share your lesson plan by writing a brief agenda on the board or telling students explicitly what they will be and doing in class. You can outline on the board or on a handout the learning objectives for the class. Providing a meaningful organization of the class time can help students not only remember better, but also follow your presentation understand the rationale behind in- class activities. Having a clearly visible agenda (e.g., on the board) will also help students stay on track. Reflecting on Your Lesson Plan A lesson plan may not work as well as you had expected due to a number of extraneous circumstances. You should have discouraged - it happens to even the most experienced teachers! Take a few minutes after each class to reflect on what worked well and why, and what you could have done differently. Identifying successful and less successful organization class time and activities would make it easier to adjust to the contingencies of the classroom. For additional feedback planning and managing class time, you can use the following resources: student feedback, peer observation, viewing videotape of your teaching, and consultation with a staff member. Conclusion To be effective, the lesson plan does not have to be an exhaustive document that describes each and every possible classroom scenario. Nor does it have to anticipate each and every student's response or question. Instead, it should you with a general outline of your teaching goals, learning objectives, and means to accomplish them. It is a reminder what you want to do and how you want to do it. A productive lesson is not one in which everything goes exactly as planned, but one in which both students and instructor learn from each other. This plan is very much effective for the general students but if the students with hearing impairment you must stress knowledge and language. Developing a lesson plan While there are many formats for a lesson plan, most lesson plans contain some or all of these elements, typically in this order: Title of the lesson Time required to complete the lesson List of required materials List of objectives, which may be behavioural objectives (what the student can do at lesson completion) or knowledge objectives (what the student knows at lesson completion) Information of Language. The set (or lead-in, or bridge-in) that focuses students on the lesson's skills or concepts-these include showing pictures or models, asking leading questions, or reviewing previous lessons An instructional component that describes the sequence of events that make up the lesson, including the teacher's instructional input and, where appropriate, guided practice by students to consolidate new skills and ideas Independent practice that allows students to extend skills or knowledge on their own A summary, where the teacher wraps up the discussion and answers questions An evaluation component, a test for mastery of the instructed skills or concepts- such as a set of questions to answer or a set of instructions to follow A risk assessment where the lesson's risks and the steps taken to minimize them are documented. Analysis component the teacher uses to reflect on the lesson itself -such as what worked, what needs improving.

163 Individual Lesson Plan: When we are modifying the teaching plan for an individual, the teacher should prepare for individual lesson plan. Now question is what is individualized education programme (IEP)? An IEP defines the individualized objectives of a child who has been determined to have a disability, as defined by federal regulations. The IEP is intended to help children reach educational goals more easily than they otherwise would. In all cases the IEP must be tailored to the individual student's needs as identified by the IEP evaluation process, and must especially help teachers and related service providers (such as paraprofessional educators) understand the student's disability and how the disability affects the learning process. The IEP describes how the student learns, how the student best demonstrates that learning and what teachers and service providers will do to help the student learn more effectively. Developing an IEP requires assessing students in all areas related to the known disabilities, simultaneously considering ability to access the general curriculum, considering how the disability affects the student's learning, forming goals and objectives that correspond to the needs of the student, and choosing a placement in the least restrictive environment possible for the student. Special education allows a child to have an individual education plan (IEP) when the child's disability interferes with the student's education and performance. Special Education is available for all children that qualify from age 3 through age 21 or upon graduation from high school, whichever comes first. If a parent feels their child requires special education, the first step is to contact the school the child is attending and explain what how you feel your child's disability will affect education. The next step is the evaluation, which will include: a letter or form from the physician explaining the child's specific medical concern interview with parents interview with teachers information from parents specific testing, including all areas related to suspected disability. After that the teacher should plan for the child according to their need. It is absolutely need based programme. Through task analysis teacher will prepare a plan. IEP plan and related matter you have already done. So here is no need to further discussion.

Remedial Lesson Plan

Each pupil is different in terms of learning ability. academic standards. classroom learning and academic performance, and each has his own in learning.

By adapting school curricula and teaching strategies. teachers can provide learning activities and practical experiences to students according to their abilities and needs. They can also design individualized educational programmes with intensive remedial support to help pupils consolidate their basic knowledge in different subjects, master the learning methods, strengthen their confidence and enhance the effectiveness of learning.

A sample plan of work for the remedial class Mode of operation: additional lessons / withdrawal (setting) / withdrawal (partial withdrawal) Year Level: Remedial Group: Teacher-: Date/ Key Stage Targets/ Reference/Resources/ Assessment Actual Remarks Language Period Forms, Functions/ Learning Activities Progress Language Skills Here are 10 strategies teachers can use to help hearing-impaired children. 1. Make sure hearing-impaired students wear amplification devices, such as a frequency modulated (FM) unit that will connect to a microphone for you to wear. 2. Use the child's residual hearing, as total hearing loss is rare. 3. Allow hearing-impaired students to sit where they think best, as sitting close to the teacher will help the child to better understand the context of your words by observing your facial expressions. 4. Don't shout. If the child is already wearing an FM device, your voice will be amplified, as it is. 5. Give interpreters copies of lessons in advance. This will help the interpreter prep

165 the student for the vocabulary used in the lesson. 6. Focus on the child, not the interpreter. Teachers do not need to give interpreters directions to give to the child. The interpreter will relay your words without being asked. 7. Only speak while facing forward. Do not speak with your back to hearing impaired children. They need to see your face for context and visual cues. 8. Enhance lessons with visuals, as hearing impaired children tend to be visual learners. 9. Repeat words, directions and activities. 10. Make every lesson language-oriented. Have a print-rich classroom with labels on the objects inside. Let us sum-up: Maxims of Teaching are the universally facts found out by the teacher on the basis of experience. They are of universal significance and are trustworthy. The knowledge of different maxims helps the teacher to proceed systematically. It also helps to find out his way of teaching, especially at the early stages of teaching. Making an effective lesson plans takes time, diligence, and an understanding of your students' goals and abilities. The goal, as with all teaching, is to motivate the students to take in what you are teaching and to retain as much as possible. Check Your Progress 1. Discuss about the maxim of teaching. 2. What is lesson plan? 3. How can make a plan for hearing impaired students. 4. What is Remedial teaching? 5. How can make a plan as remedial teaching for hearing impaired children? Reference: 1. 5.6 Partnership of Various Professional & Agencies in Educational Intervention. In order to achieve the best outcomes for all children and young people, schools must work in partnership with students, parents, other professionals and the wider community. In this changing landscape of education, the notion of the traditional school no longer exists. Partnership Working to Support Special Educational Needs & Disabilities looks at what is possible in this exciting new world, and how some teachers are putting

167 into practice the best principles of multi-agency working. Supporting children and young people with special educational needs and disabilities (SEND) in this context is more vital than ever, as more children are being diagnosed with additional needs, and those working with children are aware of the need to ensure every individual is given the maximum opportunity to develop to their full potential. In this connection various partnership and agencies is there for their better life:

1. Family As an educator, you may find that it is not as important to classify families by stages of adjustment to the child's disability as it is to understand that families have varied reactions and may work through their feelings in a different way and pace. It is helpful to realize that you and the family may not be operating at the same level or stage of understanding about the child rather than to make comments like "That family is so demanding" or "If the dad would get over his anger, we would be able to work together better" (Ulrich & Bauer 2003, 20). Listening to families is key in working with them as partners in supporting the learning and development of their child with special needs. Unless you have a child with a disability, you cannot fully understand the experience. As you get to know the child and family, it is also important to learn about and participate in the development of the child's Individualized Family Service Plan (IFSP) or Individualized Education Program (IEP).

2. Partnership with the Various Therapist (a) Audiologist An audiologist can help figure out what the problem is with a kid's hearing. He or she might send a report to the kid's doctor, so they can work together on solving the problem. Kids with hearing problems may visit an audiologist regularly to see how the treatments are working and to make sure their hearing hasn't changed. (b) Speech and Language therapist For deaf children, speech and language therapy is most effectively provided with the child's therapist to help their communication skills during everyday life. Speech and language therapist will also work closely with other professionals who may be involved with the child. Whatever communication choices you make for your child, speech and language therapy may be able

to help your child to further develop their communication skills. Speech and language therapists provide a service that takes into account the needs and wishes of your child. Speech and language therapy may be specified in a child's statement. (c) Auditory-Verbal Therapy Thanks to the improved technology in hearing aids and the availability of the cochlear implant, 95% of deaf and hearing impaired children can have access to sound. And with the right therapy, these children can learn to listen and to speak clearly and naturally like their hearing peers. This therapy is Auditory-Verbal Therapy. LSLS Certified Auditory-Verbal Therapists originally known as Auditory-Verbal Therapy was developed by Helen Hulick Beebe, an internationally-known speech-language pathologist and an educator of deaf people. It is used to enable deaf and hearing impaired children with a cochlear implant or hearing aid to listen and speak to enable them to fully participate in mainstream society. Auditory-Verbal Therapy is the therapy that is used when parents want their deaf or hearing impaired child to communicate with spoken language. LSLS professionals focus on education, guidance, advocacy, family support and the rigorous .. application of techniques, strategies and procedures that promote optimal acquisition of spoken language through listening by newborns, infants, toddlers and children who are deaf or hard of hearing.

LSLS professionals guide and coach families to help their children develop spoken language through listening, and help them advocate for their children's inclusion in mainstream schools. Ultimately, parents gain confidence that their children will have access to a full range of educational, social and vocational choices in life. The principals of Auditory-Verbal Therapy include: Early detection: Early detection programmes and initiation of Auditory-Verbal instruction upon diagnosis of the hearing loss. Appropriate amplification: The child will learn to listen and speak through maximising their residual hearing with amplification technology. Parental participation: Parent participation is vital to the success of Auditory- Verbal Therapy for two reasons: parents are the natural teachers of their child's language and the parents are always with their child so can be constantly encouraging language development. Listening to speak: The child learns to speak through listening to natural sounding

169 speech. Correct spoken models of language are crucial to teaching the child to monitor his/her vocalisations. Visual cues are not encouraged. Assessment: Monitoring and evaluating the development of listening skills as an integral part of the development process. Integration result: Appropriate amplification and Auditory-Verbal Therapy enables children with a hearing loss to develop auditory receptive skills (understanding language) in the short term that will translate via medium outcomes, such as attending mainstream school, into greater social independence and quality of life. (d) Art Therapist An art therapist is a mental health professional who uses an individual's innate creativity, usually in the visual arts, to develop social skills and self-awareness and to manage behavior and emotional conflicts. This Therapy much more effective for Hearing Impaired Children for modification of behaviour. The American Art Therapy Association explains, "A goal in art therapy is to improve or restore a client's functioning and his or her sense of personal well-being. During individual and/or group sessions art therapists elicit their clients' inherent capacity for art making to enhance their physical, mental, and emotional well-being." (e) Vision therapy Vision is a complex process that coordinates muscles, cognition and perception. Difficulty with visual motor control can lead to problems with reading, learning and executive function skills. Vision therapy, under the guidance of a developmental optometrist, can help remediate visual motor skills. Vision therapy exercises include mazes, red/green glasses, prism glasses, logic games, reading comprehension exercises, optical illusions and brain teaser games and other activities that challenge a person to understand and follow what they are seeing. (f) Special Education Services The hearing support program has a child centered philosophy for educating deaf and hard of hearing students. A variety of educational approaches and strategies are utilized and individualized according to each student's needs. This philosophy promotes effective and independent communication. The Individuals with Disabilities Education Act (IDEA '04) defines two terms related to hearing acuity: Deafness and Hearing Impairment.

According to IDEA 2004,

Deafness means

a hearing impairment that is so severe that the child is impaired in processing linguistic information through hearing, with or without amplification,

that

it adversely affects a child's educational performance. Hearing impairment means

impairment in hearing, whether permanent or fluctuating, that adversely affects a child's educational performance but that is not included under the definition of deafness.

So in this connection special educator is needed for special educational services. In the inclusive set up children with hearing impairment various agencies is needed for success of the inclusion. How partnership & Agencies working affects those children with hearing impaired. the diversity of additional needs; specialist schools; partnership working with special schools; partnership working with groups of schools; schools and other services working together; children's centers; In order to achieve the best outcomes for all children and young people, schools must work in partnership with students, parents, other professionals and the wider community. The teachers and other professionals are putting into practice the best principles of multi-agency working. Let us sum up A child with hearing impairment is identified when he /she has problem paying attention in the school, find it difficult to understand speech ,answers irrelevantly, requires repetitions of speech for following instruction, display poor vocabulary and grammar, voice problem and mispronunciation etc. Using various Audiological test for specific identification losses of hearing. In the various problems the teachers can solve easily. So that teachers should arrange the partnership of various professional & agencies. Check your progress 1. Discuss about various professionals and agencies in educational intervention. Reference:

171 A Critical Review of the Role of Neonatal Hearing Screening in the Detection of Congenital Hearing Impairment Health Technology Assessment (1997) Bamford J, Battersby C, Beresford D, Davis A, Gregory S, Hind S, Moore L, Owen Y, Reeve K Assessing Service Quality in Paediatric Audiology and Early Deaf Education British Journal of Audiology, Vol. 35, December 2001. Teachers' Perspectives on Support for Under-fives in Families of Ethnic Origin Deafness & Education International Vol 2 No 3 (2000) 5.7- Child & Family Outcomes of Educational Intervention 5.7.1- Education Intervention Education intervention is a support and educational system for very young children (aged birth to six years) who have been victims of or who are at high risk for child abuse and/or neglected as well as children who have developmental delays or disabilities. Some states and regions have chosen to focus these services on children with developmental disabilities or delays but Education Intervention is not limited to children with these disabilities. The mission of Childhood Education Intervention especially in education is to assure that families who have at-risk children in this age range receive resources and supports that assist them in maximizing their child's physical, cognitive, and social/emotional development while respecting the diversity of families and communities. Education Intervention services for children with hearing impairment yields to a better quality of life in the family. This is due to the reason that Education Intervention services to Children with hearing impairment shows a positive impact across developmental domains, including language communication, cognitive development and social/emotional development. The first few years of a child's life are a particularly sensitive period in the process of development, laying a foundation in childhood and beyond for cognitive functioning behavioural, social, and self-regulatory capacities and physical health. Yet many children face various stressors during these years that can impair their healthy development. That is why childhood education intervention programs provide supports for the parents, the children, or the family as a whole. These supports may be in the form of learning activities or other structured experiences that affect a child directly or that have indirect effects through training parents or otherwise enhancing the care giving environment. 5.7.2- Types of Educational Intervention programs in hearing impaired child. The three major types of Education Intervention programs are: Auditory-verbal: Focuses on the use of even minimal amounts of amplified hearing to develop spontaneous speech and to process language in a natural way through auditory pathways. These programs aim to enable children with hearing impairment to learn to listen, understand spoken language and communicate through speech using their residual hearing, and in the oral-aural approach, using lip-reading as well. These programs usually place the parent in the role of primary educator. Total Communication: Focuses on the use of a wide range of methods of communication including speech, lip-reading, listening, signing and finger spelling. These various methods of communication may be used alone or in combination with each other. When speech and signing are used together this is known as simultaneous communication. Simultaneous communication is used to manually represent English using a sign system known as signed English. Bilingual/Bicultural: Focuses on education through two languages. Mother tongue and second language. English is taught as a second language via reading and writing or through sign systems representing English, and speech. In many educational programs and school settings, children who are deaf or hearing- impaired may learn about the deaf community and its history, language and culture, as well as learning about the hearing community. 5.7.3-Child Outcomes of Educational Intervention: When a child's hearing loss is identified soon after birth, families and professionals can make sure the child gets intervention services at an early age. Here, the term intervention services include any programme, service, help or information given to families whose children have a hearing loss. Such intervention services will help children with hearing loss to develop communication and language skills. There are many types of intervention services to consider. We will talk about early Education intervention. So early education intervention services choices mean about education 173 and including learning to communicate with each other. Early education intervention programme will be assigned by a service coordinator to help you understand the intervention system and make sure that your child gets the services to which he or she is entitled. If proper Early Education Intervention is done, child should develop many of the factor the factors mention below: Language and speech- With the help of Early Education Intervention child can ability to learn language and speech is the highest development of children with

hearing impaired. Intellectual ability- Process of thinking of deaf children and normal peers are found to be similar in cognitive abilities and develop verbal intelligence.

So Early Education Intervention service is the most important factor of children with hearing impairment.

Academic Performance- Hearing impaired children are frequently handicapped in various degree of hearing loss and it affects educational performance and particularly reading which relies heavily upon language skill. So Early Education Intervention service is the most important factor of children with hearing impairment.
